Announcing

PERTUSSIS ANTIGEN (Detoxified)

Lederle

THIS new form of therapy is recommended for the treatment of active cases of Whooping Cough as well as in general prophylaxis.

Free from bacterial cells, "Pertussis Antigen (Detoxified) *Lederle*" is a departure from the usual form of vaccine therapy. Based upon a toxic principle derived from *H. pertussis*, treatment with formalin converts the toxic factor into a non-toxic substance having antigenic properties.

If used early in *treatment* or soon after exposure, the immunological response is sufficiently rapid to modify or prevent, respectively, the disease in the majority of cases, as evidenced by the following:

49 of 53 cases treated during the first or second week did not develop whooping or vomiting.

Of 70 cases treated during the third or fourth week, 30 became symptom-free after the completion of injections, while the remainder showed marked improvement but continued to run a mild, modified course of whooping cough. Cases treated during the fifth week showed no benefit.

When used for *prevention*, only 3 out of 140 developed the disease and those 3 were mild atypical cases.

SAFETY and CONTROL

RETESTED
K
BLUE
LINE

for assurance

IN THE GREAT DAIRY INDUSTRIES

One of the most far-reaching and envied assets of the nation is its vast Dairy Industry, producing almost 110,000,000,000 pounds of whole milk each year. 20% of the consumer's food dollar goes for milk and milk products—more than \$385,000,000 in butter, \$57,000,000 in cheese, \$131,000,000 in condensed and evaporated milk. All told, this amazing industry tips the financial scales at about \$4,000,000,000 a year!

Kimble Blue Line Exax Glassware is a very definite and vital factor in helping maintain the rigid control and high quality of dairy products. The accuracy of Blue Line Exax in test, analysis and research—whether in dairy laboratories, or in chemical or industrial plants, clinical or medical institutions—gives that ASSURANCE so essential to scientific success.

Standardize, for safety and service, on Blue Line Exax—with its brilliant BLUE fused-in calibrations, its retested, annealed and strain-free construction—for all chemical, biological and clinical determinations.

*Stocked by leading Laboratory Supply Houses
throughout the United States and Canada*

"Early" is the watchword in

PNEUMONIA CONTROL

IN A RECENT ISSUE OF THE HEALTH OFFICER, the following watchwords were promulgated for the control of pneumonia:

"*Early* diagnosis, *early* typing and *early* serum treatment mean *early* recovery."

The importance of *early typing* cannot be over-emphasized, for it not only serves to identify the specific etiologic agent of the pneumonia, but frequently, and especially in atypical pneumonias, it also aids in fixing the diagnosis and makes possible the early administration of specific serum.

The Neufeld Rapid Typing reaction should be applied to the patient's sputum immediately upon suspicion of lobar or bronchial pneumonia.

"Pneumococcus Typing Serum *Lederle*" Types 1 to 32 for the Neufeld Reaction, ready for immediate use, are available in 1.0 cc. vials and in packages of 5 capillary tubes for individual tests.

An editorial in the December 4, 1937 issue of the Journal of the American Medical Association states:

"In view of the distribution of pneumonia and the known effectiveness of serum when given early in the most fatal types, the facilities for typing are of the utmost importance."

A printed list of 2000 laboratories in the United States and Canada to which sputum may be referred by practitioners for typing has been published in directory form by Lederle and may be obtained free on request to

PROMOTES HEALTH AND SANITATION IN THE HOME

Electric Sink..

WITH DISHWASHER AND DISPOSALL

Washes and Dries the Dishes Hygienically Clean... Quickly Disposes of Kitchen Food Waste at the Sink

• The General Electric Sink "does the dishes" and disposes of food waste electrically. Dishes, silverware, pots and pans are cleaned hygienically in water at pasteurization temperature—140 to 160 degrees—far hotter than human hands can stand. Dishes and utensils dry in their own heat. No unsanitary dishcloths! All food wastes—even chop bones—go down the drain into the Disposall where they are

shredded to a thin pulp and flushed away like water. No more messy garbage! No more odors! No more disagreeable trips outdoors to the germ-breeding garbage can! The G-E Dishwasher may be installed as a separate cabinet and the G-E Disposall can be attached to almost any home sink. The G-E Electric Sink combines Dishwasher and Disposall. It's the sanitary, work- and time-saving way to take care of the two most unpleasant kitchen tasks. Let us send complete details. Write today to General Electric Company, Section AJ2, Nela Park, Cleveland, Ohio.

DARK FIELD

The program of the national public health service for the eradication of syphilis includes widespread use of the dark-field test for *Treponema pallida*. This promotion of a microscopic technique emphasizes the general value of advancement in optical science.

Spencer scientists and craftsmen whose products have earned the special praise of technicians in dark-field work, are consistently advancing the optical quality of all Spencer instruments.

In every application of microscopy the Spencer standard of "Optical Quality First" merits your attention.

IMPROVED DEFINITELY LESS IRRITATING

CIGARETTES made by the ordinary method of manufacture produce an irritation of the nose and throat that is noticeably absent when smoking Philip Morris.

Scientific research* shows that cigarettes in which diethylene glycol is used, are definitely less irritating—a major improvement in cigarettes.

In Philip Morris diethylene glycol is used exclusively as the hygroscopic agent.

Reducing the risk
of severe serum reactions in

SCARLET FEVER ANTITOXIN THERAPY

TIME WAS WHEN PHYSICIANS confronted with a case of scarlet fever felt themselves in a dilemma. The use of antitoxin meant a serious risk of serum reactions; withholding it left the patient in danger.

Antitoxin was, therefore, frequently given only in severe cases; with the result that many of the milder cases progressed to the severe form of the disease, with a lower expectancy of effectiveness of serum therapy when instituted late.

The advent of "Globulin Modified Scarlet Fever Streptococcus Antitoxin *Lederle*" has changed the old attitude towards antitoxin therapy.

This potent antitoxin with its greatly reduced liability to cause reactions is now being widely used regardless of apparent mildness of attack. The decrease in the incidence of serious complications alone, aside from the favorable effect on the prognosis, far over-balances the lingering hazards involved in the 2% incidence of severe serum reactions following the use of this antitoxin.

"Scarlet Fever Streptococcus Antitoxin (Globulin Modified) *Lederle*" is available in appropriate packages for both prophylaxis and therapy.

SHE SAYS

"Please" AND "Thank You"

THE alert, courteous voice of the telephone operator is known to all who use the telephone.

To the little old lady in the shawl, the man in the big house on the hill, or a tiny tot of six, the words are the same, "Number, please" and "Thank you."

The Bell System appreciates your patronage and tries to deserve it. In everything that concerns telephone service, we hope you can say: "They're nice people to do business with."

MOVING MOUNTAINS

THROUGH CHEMISTRY

Best Assurance

Through the power of explosives, impassable mountain ranges bow to the engineer's command—railroads, bridges and dams follow in the wake of these man-made earthquakes. Construction rides on apace each year as over 300,000,000 pounds of dynamite, nitroglycerine, blasting powder and other permissible explosives carve the way. In 1935 over \$40,667,000 worth of these products were consumed by the quarry, mining and construction industries.

The exacting quality control of this violent but useful power depends greatly on Kimble Blue Line Exax. In the great industrial and research centers—in chemical plants, clinical and medical institutions—Blue Line Exax has placed control, test and analysis on a higher plane of accuracy and ASSURANCE. The easy-to-read, brilliant BLUE fused-in calibrations, and the highly annealed (strain-free) construction of established standard of industry and science—for safety and service.

Stocked by leading Laboratory Supply Houses throughout the U. S. and Canada

For early treatment and prophylaxis of

WHOOPING COUGH

WHOOPING COUGH is not an innocuous disease; its death rate during the first three months of 1937 was greater than those from diphtheria, measles and poliomyelitis combined. (U. S. Public Health Reports)

When it is considered, moreover, that by far the largest proportion of these deaths is concentrated in the lowest age group (under 3 years), the problem of whooping cough becomes the acute concern of child health authorities.

Clinical experience with the new "Pertussis Antigen (Detoxified) *Lederle*" in the treatment of early cases, or in the prophylactic treatment of exposed children, gives hope that in this immunizing antigen we have an unusually effective agent for use under epidemic conditions.

Used early in treatment, the disease has been modified and its course shortened.

Used for the prevention of whooping cough among exposed children, only a very small percentage have developed symptoms, and these were mild in character.

This new antigen is non-toxic, free of bacterial cells and contains a minimum of autolytic products.

PERTUSSIS ANTIGEN *Lederle*

Packages:—3 vials—2 cc. each
1 vial—20 cc.

HEALTH OFFICIALS ENDORSE G-E ELECTRIC SINK WITH DISHWASHER AND DISPOSAL

MUNICIPAL health officials praise the G-E Sink as a modern, sanitary convenience which eliminates two of the most unpleasant kitchen tasks.

The General Electric Sink combines Dishwasher and Disposall. With the G-E Dishwasher, dishes, silverware, pots and pans are washed hygienically in water at pasteurization temperatures . . . far hotter than human hands can stand. Dishes dry in their own heat. No more unsanitary dishcloths and towels! With the G-E Disposall, all food wastes—even chop bones—are shredded to a thin pulp and washed away down the drain like water. No more messy accumulation of garbage! No more trips outdoors in all kinds of weather to the unsightly, germ-breeding garbage can! Let us send you descriptive literature. Write today. General Electric Company, Specialty Appliance Div., Sec. AJ4, Nela Park, Cleveland, O.

Control **SCARLET FEVER**

MUCH REAL PROGRESS has been made in recent years toward the control of scarlet fever, but despite this fact there are still more than 200,000 cases reported annually in the United States.

There is, therefore, urgent necessity for bending every effort toward abolition of scarlet fever; an end which is readily attainable through proper use of available preventive and curative measures.

The dependable potency and clinical effectiveness of Squibb Scarlet Fever Products make them preparations of choice in a number of institutions and with department of health authorities. They serve equally well the physician in general practice.

Warm Days and the

RABIES MENACE

IN THE SPRING OF 1937, the state of Illinois experienced a sharp increase in the incidence of dog-bites as compared with 1936, which, too, had been an alarming year. At the same time there was an increase of over 50% in the number of dogs found positive for rabies.

Despite this increase in rabies among animals the human mortality rate has been maintained at a low figure by the prompt administration of anti-rabies vaccine to those exposed.

Since 1922, the state of Alabama records 9,800 Pasteur treatments with a 0.11% mortality, and 25,064 Semple treatments with a 0.04% mortality.

In the face of this proven effectiveness of anti-rabies vaccine, it seems criminal to postpone the initiation of treatment pending the finding of a positive pathology in the animal. The safe way is to start treatment immediately after exposure and to halt the injections if the animal is found to be negative.

RABIES VACCINE (SEMPLÉ METHOD)

Lederle

is available in the 14-dose vial set with syringe and two needles. A supplementary 7-dose set, for use in cases where the bite is severe or where treatment has been delayed, is also obtainable.

\$2,600,000,000 IN TEXTILES

Greatest American industrial group in number of wage earners employed—in number of large plants and of electric motors installed, and second in rank in value of its products—is the textile industry. From almost 6000 textile mills in the U. S. come knit goods, woolens, silks, rayons, linens, felts, cottons, etc., valued annually at over \$2,600,000,000. To operate this vast industrial group requires \$30,000,000 worth of belting, 4,000,000 horsepower, and \$79,000,000 worth of textile machinery!

Safeguarding this mammoth investment are the modern textile chemical laboratories which control production, perfect new processes, and produce newer and more useful products. And into these great plants goes an ever-increasing quantity of Kimble Blue Line Exax Glassware—for research and control, for protection to quality and profits.

Similarly, in every phase of the chemical and process industries—in every great clinical and medical center—you will find Kimble Blue Line Exax Glassware carrying on its endless task of scientific protection to investments, to results, and to life itself.

When you buy Laboratory Glassware, buy for safety and ASSURANCE. Specify Kimble BLUE LINE EXAX!

Entered as second-class matter at the Post Office at Albany, N. Y., September 17, 1932.

In severely contused wounds and puncture wounds —

TETANUS ANTITOXIN

[GLOBULIN **Lederle** MODIFIED]

SEVERELY CONTUSED WOUNDS and puncture wounds with penetration of foreign material are of the type most likely to be followed by tetanus.

Prophylactic tetanus antitoxin should be administered as early as possible after—

FIRECRACKER WOUNDS
BLANK CARTRIDGE WOUNDS
GUNSHOT WOUNDS

PUNCTURE WOUNDS
MACHINERY WOUNDS
COMPOUND FRACTURES

CRUSHED WOUNDS

"The teaching that tetanus will not develop in a drained wound is fallacious. The practise of not giving prophylactic doses of antitoxin in cases of puncture wounds is dangerous."*

In recent years the practise of giving 3,000 units of Tetanus Antitoxin instead of 1,500 units, the dose formerly recommended, has become more common.

"Tetanus Antitoxin (Globulin-Modified) Lederle" is so markedly concentrated and purified that the 3,000-unit dose is contained in a volume of 1 cc. With the "Globulin-Modified" antitoxin the incidence of reactions remains negligible despite the increase in potency.

*Bunch, Geo. H., Southern Medicine & Surgery; July, 1937.

In the treatment of tetanus, it is indicated that whatever benefit may be derived from antitoxin is probably due to that antitoxin which is administered early. Clinical reports suggest that large doses (100,000 to 200,000, or even more) be given immediately upon diagnosis.

Packages:

"TETANUS ANTITOXIN (GLOBULIN-MODIFIED) Lederle"

For Prophylaxis

1,500 units in syringe
3,000 units in syringe
1,500 units in vial

For Treatment

10,000 units in syringe
20,000 units (intraspinal outfit)
20,000 units in syringe
40,000 units in syringe

RELIABLE ADVERTISEMENTS

SQUIBB ANTITOXINS

Always Dependable

EXTENSIVE RESEARCH in the Squibb Laboratories has resulted in important improvements in the processes used to concentrate and refine antitoxic globulins. As a result, Squibb Antitoxins are distinguished by a high degree of purity, clarity, and freedom from reaction-producing proteins.

Squibb Antitoxins are isotonic with the blood and rapidly absorbed with very little pain or danger of serum reactions.

VITAMIN B₁ FOR IMPROVED INTESTINAL TONE

Because recent studies have shown that vitamin B₁ has a beneficial effect on the tone of the intestines, this vitamin is receiving more and more attention as an aid in treating atonic constipation.

A good source of vitamin B₁ is Kellogg's All-Bran. Notice below how the vitamin B₁ content of All-Bran compares with that of other foods.

The presence of this vitamin, in such plentiful quantities, in a food which also contains natural "bulk," is being recognized as a further reason for recommending this laxative cereal.

IT TAKES

2 OZ. OF SPINACH, OR	
2 ¹³ / ₁₆ OZ. OF WHOLE EGG OR	
2 ¹ / ₈ OZ. OF WHOLE ORANGE,	
TO SUPPLY THE AMOUNT OF B ₁ CONTAINED IN 1 OZ. OF	

**Kellogg's
ALL-BRAN**
A Natural Laxative Cereal

The SWING to PHILIP MORRIS

THE rapid increase in Philip Morris sales is unquestioned evidence of America's growing appreciation of a superior product.

Of no little consequence in making Philip Morris a superior cigarette is the decrease in irritation due to the use of diethylene glycol as hygroscopic agent.

Banishing Diphtheria with

REFINED DIPHTHERIA TOXOID
(ALUM PRECIPITATED)*Lederle*

STATISTICS AMPLY SUPPORT the value of diphtheria immunization. The need for a universal immunizing program is emphasized by the observation⁽¹⁾ that:—

"... wherever preventive inoculation against diphtheria is practised consistently, diphtheria deaths well-nigh cease to occur, and in some communities diphtheria morbidity is also reduced to an insignificant figure".

The effectiveness of Alum-Precipitated Toxoid as an immunizing agent is demonstrated by the figures presented by Saunders (Lancet, 1937, 1, 1065), following a study of 2,157 children, treated with a single 1 cc. injection of Alum-Precipitated Diphtheria Toxoid.

Interval after injection	Cases Tested	Schick Negative (%)
5 weeks	867	94.4
6 weeks	446	99.3
7-9 weeks	304	99.0
10-12 weeks	182	100.0
Over 12 weeks	358	99.4

Havens' method for single injection immunization is calculated to meet with a greater degree of public cooperation with immunizing programs.

"Refined Diphtheria Toxoid (Alum-Precipitated) *Lederle*" is designed to provoke a rapid lasting immune response, with a minimal incidence of unpleasant reactions.

For those who desire to employ the multiple-dose method of immunization by means of plain toxoid, "Diphtheria Toxoid (Plain) *Lederle*" is also available.

"THANKS FOR CALLING"

The telephone helps a lot of folks to know each other better. Business is easier—friends are nearer—life is richer—because of it.

"Thanks for calling," spoken over the telephone many times a day, is a friendly reminder of the usefulness, dependability and value of Bell System service.

KIMBLE BRAND

For Assurance WEIGHING BOTTLES

WITH OUTSIDE GROUND CAPS

(CATALOG No. 15146)

*Featuring 8 Advantages
Every Chemist Wants!*

- 
- ① The cap protects the top of the bottle from breakage when the bottle is tipped over.
 - ② Material within the bottle does not come into contact with any ground surface.
 - ③ Elimination of penny head top removes one source of breakage.
 - ④ Bottle and stopper are so designed that an air tight joint is assured.
 - ⑤ Increased head room provided by the stopper decreases danger of fluffy material being sucked out when stopper is removed.
 - ⑥ No chance of contamination of contents from dirt, such as occurs with the old style bottle.
 - ⑦ Bottles and stoppers have large, plainly visible corresponding serial numbers.
 - ⑧ Every bottle has a small sandblasted area suitable for pencil inscriptions.

Probably the most easily preventable disease is

SMALLPOX

—And yet SMALLPOX has been appearing with a more and more disheartening frequency of late.

Four years ago it seemed that this dangerous disease was at last coming under control and that it was only a question of time when smallpox would be finally eliminated as a major health problem in this country; but, the accompanying chart shows how far from this goal we are to-day.

From the Statistical Bulletin, Metropolitan Life Ins. Co., 19: No. 5 (May) 1939.

By the application of the relatively simple procedure of universal vaccination, and at a nominal cost per person, Smallpox can be completely banished. This has been proven in certain foreign countries where universal vaccination has been strictly enforced, with the result that they have been entirely free from the disease for years.

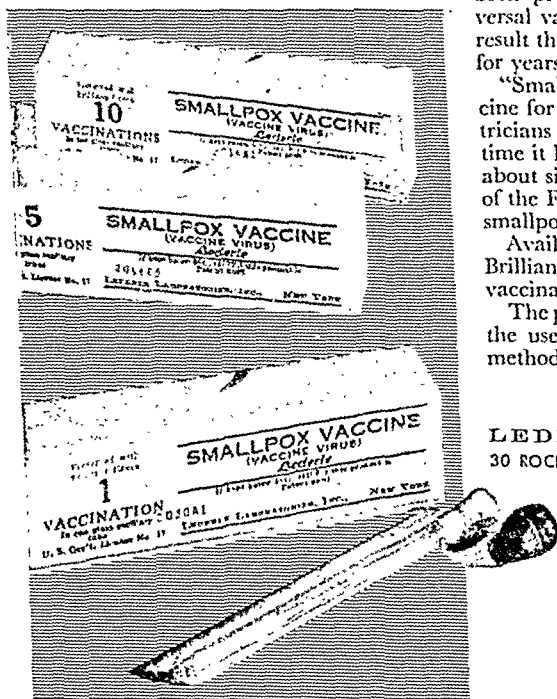

"Smallpox Vaccine Lederle" is a safe, effective vaccine for use in immunization against smallpox. Pediatricians recommend that a child be vaccinated by the time it has reached the age of six months and again at about six years of age (preferably before the beginning of the Fall school term), and whenever an epidemic of smallpox is present.

Available in two forms; U.S.P. and "preserved with Brilliant Green", in capillary tubes for 10, 5 and 1 vaccination each.

The pressure puncture method of vaccination without the use of a shield or dressing is recommended as a method of choice by the National Institute of Health.

Some micro-organisms are so similar in refractive index and color to the medium in which they live that they cannot be seen in the ordinary bright field. Such organisms can be identified easily with the new Spencer dark field microscope because the illumination strikes them from the sides in a dark field, making them self-luminous.

This new Spencer microscope is specially designed as a time saving routine instrument. The substage, with built-in illuminant, is hinged to the stand, thereby holding the dark field condenser and the illuminant in positive alignment with the objective as centered at the factory. The hinged substage facilitates placing oil on and cleaning the condenser.

This instrument is of traditional Spencer quality throughout and is moderately priced.

Write Dept. H19 for new bulletin giving complete description.

Kellogg's ALL-BRAN

SUPPLIES:

○ Many foods of fibrous content have been suggested as a source of laxative bulk. Such bulk is not available as an eliminating agent, however, unless it reaches the colon undigested.

The effectiveness of Kellogg's All-Bran as a source of bulk lies in the fact that in the average person a large part of its fibrous content does not digest, but provides an ideally soft bulky residual mass in the intestine.

In addition, All-Bran furnishes a significant amount of vitamin B₁, beneficial to the intestinal tonus. Also as a source of iron, All-Bran is especially valuable ... because in All-Bran the iron occurs with copper, thus becoming readily available for making hemoglobin.

These contributions by Kellogg's All-Bran to important physiological functions suggest its use as a dietary aid in constipation resulting from lack of bulk. Made by Kellogg in Battle Creek.

YOU WANT FACTS

It is facts that you want. Not hearsay, nor claims.

Tests were made on five brands of cigarettes to determine their irritant properties. Conclusively these tests prove the definite superiority of Philip Morris.

Reprints of these findings — as well as other researches on the subject of irritation due to smoking — all published in medical journals* — will be sent you on request.

Reliable tuberculin testing
without the use of a needle

TUBERCULIN PATCH TEST (Vollmer)

Lederle

THIS NEW TEST is designed to assure less resistance on the part of the patient and his family to the active program now being conducted to unearth, by tuberculin testing, hitherto undiagnosed cases of tuberculosis.

After cleansing the skin with acetone, the patch is applied like an ordinary strip of adhesive, left in place for 48 hours and the reaction is read 48 hours later.

The patient's dread of the needle and the nervous excitation attending the preparations for injection cease to exist as deterrents to the systematic testing of children at home or in schools. Groups in schools and hospitals may often be thus tested without the trouble of obtaining the parents' permission.

"Tuberculin Patch Test (Vollmer)" is accurate, comparing favorably with the Mantoux test. It differs from other patch tests in that the area of reaction is sharply defined and does not spread.

The test is safe; no focal or general constitutional reactions have been reported.

A pledget of cotton, damp with acetone, is all the extra equipment needed to apply the test.

Packages:—1, 10 and 100 tests.

*Supplied in packages of
1, 10, and 100 tests.*

**For
Improved
Milk Quality...
FRIGID
FILTRATION**

IMPROVED milk quality results from filtering milk at 40° F. with the Rapid-Flo Frigid Filter. Sediment is removed as the first operation in the milk plant, before heat is applied. Hot bag filtration tends to dissolve foreign substances. The number of cities with ordinances forbidding hot filtration is increasing all the time. The cost of Frigid Filtration to the

dairy is a fraction of a cent a quart. Frigid Filtration is now in satisfactory daily use in over 200 milk plants. Milk sanitarians and health authorities will be interested in this new process for better milk. The story is told in "Frigid Filtration," copies of which will be sent, gratis, on request to Johnson & Johnson, New Brunswick, N. J. Send for your copy today.

BEHIND YOUR GOOD TELEPHONE SERVICE

IS THE *Constant Courtesy* OF

THE VOICE WITH A SMILE

THE MAN ON THE JOB

THE MEN AND WOMEN
IN THE TELEPHONE OFFICE

This country is entitled, in good times and bad, to the best telephone service at the lowest possible cost.

A great factor in accomplishing this is the real spirit

of service that has become a tradition among telephone men and women. Courtesy and efficiency are important words in the Bell System.

Type all pneumonias—

PNEUMOCOCCUS TYPING

RAPID—ACCURATE

THE NEUFELD METHOD of type diagnosis has made specific serum therapy practicable.

Typing directly from sputum frequently permits a type diagnosis within a few minutes.

Early specific treatment—so vital to successful serum therapy—is possible only when the pneumococcus type is determined *early*.

Therapeutic sera are now available for a greater number of pneumococcus types. Approximately 75% of all adult pneumococcus pneumonias can be treated by means of specific sera for Types 1, 2, 4, 5, 7, and 8.

"Diagnostic Antipneumococcic Sera (Rabbit), *Lederle*" for typing by the Neufeld reaction, are available in the following packages:

1.0 CC. VIAL

5 capillary tubes for individual tests for each of the monovalent Types and for the following combinations:—

Mixture "A"—containing Types 1, 2 and 7

Mixture "B"—containing Types 3, 4, 5, 6 and 8

Mixture "C"—containing Types 9, 12, 14, 15 and 17

Mixture "D"—containing Types 10, 11, 13, 20, 22 and 24

Mixture "E"—containing Types 16, 18, 19, 21 and 28

Mixture "F"—containing Types 23, 25, 27, 29, 31 and 32

Lederle

These cases will be furnished to hospitals free of charge with orders for complete typing material.

Spirochaeta Pallida

The New EVERSON "Automatic Vacuum Control" CHLORINE STERILIZER

This new Chlorine Control Apparatus is the result of extensive work in developing and perfecting Chlorine equipment especially adaptable for water works and sewage applications.

This new instrument measures and feeds Chlorine Gas as a solution, has many new and improved features which make it automatically safe and accurate. Briefly it embodies the following designed features: Accurate, visible control of gas flow; Great capacity range—ratios from $1\frac{1}{2}$ to 65; only two moving parts; single valve control automatic gas shut-off; electrically operated water shut-off—synchronizes "on" and "off" of sterilizer with that of pump; complete vacuum feed, water sealed gas vent with that of pump; all parts easily accessible and entirely noncorrosive—parts which contact chlorine as gas or in solution are rubber, glass, silver or tantalum; Standard (SAE) threads and parts for easy servicing, etc.

This new Sterilizer, which though complete in up-to-the-minute features, will be in the "low price field". Write for complete data!

Probably 70% of all cases of
lobar pneumonia can be treated with—

ANTIPNEUMOCOCCIC SERA

TYPES 1, 2, 4, 5, 7 AND 8

WITH A RESULTANT saving of over 40,000 lives
annually in the United States.

IN RECENT YEARS an average of 100,000* deaths per
year have been attributed to lobar pneumonia alone.

Calculating from the known relative frequencies
of the individual pneumococcus types, and from the
mortality rate when no serum is given, 225,000 cases
and 67,000 deaths are caused by Types 1, 2, 4, 5, 7,
or 8, pneumococci.

19 out of every 31 deaths can be avoided* by ade-
quate specific serum therapy, administered during the
first four days of illness; in other words, more than
40,000 of these deaths are preventable.

Potent, refined and concentrated "Antipneumo-
coccic Sera *Lederle*" are available in the
following packages:

Bivalent Types 1 and 2, Bivalent Types
4 and 8, Bivalent Types 5 and 7, Mono-
valent Type 1 and Monovalent Type 2.
These are horse sera and are all "Council
Accepted".

A survey of the literature indicates
that the types enumerated here are
responsible for more than 70% of all
cases of pneumococcic infection, no
matter how manifested (lobar or bron-
chial pneumonia, empyema, etc.).

THE VOICE WITH A *Smile*

NORTH

SOUTH

EAST

WEST

It may carry the salty twang of New England or the soft accents of the South.

It may be swift and crisp in the New York manner or full of the pleasant rolling r's in the style of the West.

But wherever you hear it, it will be friendly, courteous, and efficient.

It's the all-American voice of the Bell Telephone operator -- "The Voice with a Smile."

The entire Bell System seeks to serve you quickly, capably and in the spirit of a friend.

BELL TELEPHONE SYSTEM

The Bell Telephone System is the most reliable in the world.

Prevent the dangerous complications of

WHOOPING COUGH

WITHIN RECENT YEARS, the mortality from whooping cough has exceeded the death rate from diphtheria, scarlet fever and measles combined. Whooping cough is nearly if not quite as contagious as measles and far more dangerous to children in the earliest age groups.

The main cause for concern, when whooping cough occurs, remains the high incidence of complications—chiefly bronchopneumonia.

"Pertussis Antigen (Detoxified) *Lederle*" offers a promising agent for the control of this disease. Clinicians have reported favorably concerning this product when it is used early in the course of the disease. The use of this

product for the prevention of whooping cough in intimately exposed contacts has also given gratifying results.

Most striking has been the observation that the incidence of interstitial or bronchial pneumonias has been sharply reduced in cases treated with this antigen.

as an aid to
elimination

- 1 Medical authority concedes that "bulk," provided by food residues, assists efficient elimination.
- 2 Medical authority ascribes to vitamin B₁ the important property of improving the tonus of the intestines.

Regular use of Kellogg's All-Bran supplies helpful "bulk." This food also contains vitamin B₁ in appreciable quantity.

These facts provide a sound medical basis for recommending Kellogg's All-Bran as a valuable aid in the prevention or relief of constipation due to lack of "bulk." Made by Kellogg's in Battle Creek.

A NATURAL LAXATIVE CEREAL

Lifetime
Precision Features

The many exclusive mechanical refinements built into the Spencer No. 33 MH Microscope assure "new instrument accuracy" throughout a lifetime of use.

1. Forged brass arm, of fine homogeneous grain structure provides lasting strength and rigidity and retains its original trueness.
2. Micrometer type fine adjustment with chromium plated slide bearings and specially designed oil grooves, guarantees smooth operation and enduring accuracy.
3. Dual-cone nosepiece with twice the usual bearing surface maintains more accurate alignment of the objectives.
4. Fork-type substage facilitates convenient interchange of condensers and provides permanent optical alignment.
5. Bright parts plated with rhodium assure maximum resistance to chemical reagents.

"Lifetime Precision" is the creed of Spencer scientists and craftsmen.

An Equal Opportunity for Health*

THE HONORABLE HERBERT H. LEHMAN

Governor of the State of New York, Albany, N. Y.

SIXTY-SIX years ago, on April 18, 1872, New York City became the birthplace of this Association, when your founders first met here to formulate the basic principles of public health coöperation which have now permeated the nation. You have honored both the city and state of your birth by coming home from time to time so that we can rejoice in your splendid progress.

Now, in your maturity, we welcome you home once again.

You may recall that the late Stephen Smith, your distinguished first President, who only a few years ago died at the age of 99—placed the normal duration of human life at 100 years instead of the biblical span of three score and ten. The practical realism of Dr. Smith's prophecy is revealed in the fact that since 1900 ten whole years have been added to our life span.

It is my firm conviction, often repeated, that so far as science and government can make it possible, an equal opportunity for health is the right of all citizens of the community,

regardless of circumstances, birth, economic conditions, geographical limitations, race, creed, or color.

Public interest in hygiene and health can be made effective only when it can be concentrated in the carrying out of a definite plan. This plan should be subject to continuous revision so that full advantage may be taken of both scientific and administrative improvements in the field of public health.

Definite plans require expert preparation and supervision, with official recognition of the maxim that the health of the people is indeed the highest law.

I am proud to be able to say that during the past quarter century the State of New York has recognized the full logic of the statement made in 1913 by that eminent physician and humanist, Sir William Osler, when he said: "Were the health of the people made a question of public and not of party policy, only a skilled expert could possibly be appointed as a public health officer, not, as is now so often the case, the man with the political pull."

Suffice it to say that the guidance of the public health activities of the State of New York since 1914 has been in

* Presented to the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

the hands successively of Hermann M. Biggs, Mathias Nicoll, Jr., Thomas Parran, and now Edward S. Godfrey, Jr., all eminent practitioners of your profession and appointed solely on the basis of their outstanding technical and personal achievements in the field of public health.

The record speaks for itself. In 1913 the death rate in the state for all communicable diseases was 419 per 100,000 population; in 1936 it was 151—a decrease of 64 per cent. Tuberculosis mortality has declined more than one-half since 1913; and the general death rate has declined almost 24 per cent. Both typhoid fever and diphtheria, once very prevalent, are now rare diseases both with a death rate of 0.5 per 100,000 population.

If the death rates of 1913 from these several causes had continued to prevail, there would have been in 1936, 48,000 more deaths from all causes in New York State. Of the infants now living, 11,300 would have died. Additional deaths from tuberculosis would have amounted to 12,400; typhoid fever, 1,300; and from diphtheria, 2,500.

That the economic condition of a community bears a very direct and potent relation to the health and welfare of its citizens is a conviction which has continued to grow upon me for many years.

In 1933 we were in the midst of an economic cataclysm that affected the well-being of every man, woman, and child, and threatened the security even of the state itself. Fear and panic were on every hand. Thousands were without adequate food, shelter, or work. Man was stunned and bewildered by forces which engulfed him and from which there appeared to be no escape. Man had lost hope. New York, like her sister states, had suffered in the midst of national and international adversity. Like all other

governments, the State of New York faced the problem of fitting its aspirations of public service into the reduced limits of its treasury.

I said in 1933 and repeat now: "The significant thing is that financial considerations have not compelled us to waver too greatly from our ideals of the community services which the state must perform . . . essential protection for the security and well-being of our citizens still persists. I pray it will always continue to persist in our enlightened commonwealth."

Conditions during those trying days required immediate relief through emergency legislation and emergency administration.

Our laws quite simply recognized the responsibility of the state to provide food, clothing, shelter, and medical care for those who otherwise would be without it. In spite of decreased public revenue our state has maintained the lead among all others of the nation in the relief of the distress of unemployment. The legislature has appropriated state funds to help cities and counties give the necessities of life to those who were temporarily dependent through no fault of their own. At one time, more than one-sixth of the population of the state, including 800,000 or one-fourth of all our children, were provided with these necessities of life. The total expenditure of public funds in the state in nearly 6 years of public assistance, amounts to approximately one and one-quarter billions of dollars.

To achieve our goal of an equal opportunity for health and adequate medical care, we have emphasized that there must be an increasing degree of whole-hearted coöperation between public health officers, private physicians, and the welfare agencies of any community.

During the economic crisis, emergency action was necessary. We have

followed the famous advice given by John Hunter to his illustrious pupil, Edward Jenner, when he said, "Don't stop with thinking, try!" By both trying and thinking during the past 5 years, emergency action has become less and less necessary. Permanent social and economic reforms have been planned and executed.

Let me review for you some evidence of the ways in which this permanent protection is being developed for the health of citizens of New York State.

Since January 1, 1933, with my full support as Governor of this state, for a period of almost 5 years, a concerted attempt has been made to develop and provide for each locality an equality of opportunities for adequate public health and medical services.

The new activities and programs which have been undertaken or extended have not been stereotyped in pattern but have been sufficiently flexible so that new methods and administrative policies could be developed and tested—in the cold light of the effectiveness with which they provide adequate health services to the individual citizen and the extent to which they represent an efficient expenditure of public moneys.

The most significant new activity conducted by the Department of Health of the State of New York involves an unremitting effort to secure a thoroughgoing reorganization of local health services to the end that disparities might be eliminated and that the support of adequate services might be spread more economically over a larger tax base.

Conceivably the objective could be achieved in one of two ways—namely, by the promotion of county health departments with financial assistance from the state, or by the provision of necessary professional and technical serv-

ices by the state itself through expansion of state health district activities. To eliminate the inadequacies and disparities in the town and village systems for health service, emphasis during the past 5 years has been placed upon both of these alternative methods.

My good friend, Thomas Parran, then State Commissioner of Health—now Surgeon General of the U. S. Public Health Service and President of your Association—in his annual report to me for the year 1934, said: "In spite of the material financial inducement to counties to organize health departments, little progress can be recorded in 1934. The present town and village system for health service is inadequate. The people in the rural areas are sorely in need of more effective health protection measures. If the counties, themselves, are unwilling with state aid to organize the health services, the only alternative seems to be for the state, itself, to operate many services heretofore considered a local responsibility."

Edward S. Godfrey, Jr., our present Commissioner of Health, said, later in the year 1935, in a public address: "I submit that local interest and support can be developed for a system of state districts each under a whole-time health officer as well as for a system of locally operated departments. Public health service always expresses itself locally, whether in services to an individual, a family, a group, or to a community."

The record shows my hearty endorsement of the practical suggestions made by these two outstanding public health administrators.

Now, in 1937, I am happy to announce the fruition of certain projects in which I have been deeply interested during my service as Governor. These include: The rebuilding of the State Reconstruction Home at West Haverstraw—to provide adequate and mod-

ern facilities for the treatment of remediable crippled children; the completion and opening of three new state hospitals for tuberculosis; the inauguration of expanded programs for the control of syphilis, pneumonia, and cancer; the better implementing of the District Offices of the State Health Department—for the development of broader and better local health services; and, the tremendous progress which has been made in the construction of needed sanitary improvements in the municipalities of this state during the past 5 years—under the stimulus of state and federal aid.

Today we have more than 12 million of our citizens resident in communities served by public water supply systems under the supervision of the engineers of the State Department of Health. With respect to the elimination of objectionable pollution in our own and neighboring states we have achieved more during the past few years than in the preceding three decades. More people are served by sewage treatment works constructed in this state since 1933, than are served by all such plants constructed prior to that date.

Sanitary supervision over some 3,000 camps, 3,000 summer hotels and 2,000 artificial swimming pools is doing much to safeguard the health of almost 3 million persons annually among the vacationing and traveling citizens of this and other states.

We point with pride to the pioneer work by our Bureau of Milk Control and other divisions of the State Health Department in the experimental development and practical application of the newly adopted phosphatase test, to determine the efficiency of pasteurization, which bids fair to revolutionize milk control policies throughout the United States.

Tremendous strides have been made

by New York State during the past few decades in the reduction of deaths from certain causes by the application of principles of medical and sanitary science. Yet, in the light of present knowledge, much further improvement is obtainable.

An estimate by an eminent authority, Louis I. Dublin, of the Metropolitan Life Insurance Company, if applied to Continental United States, reveals a possible saving of about 600,000 lives every year, of whom about one-fourth, or 125,000, would be children in the first 5 years of life. One-tenth of this potential saving could be attained conceivably in New York State alone.

To achieve this goal, present local health services must be maintained; victories over specific diseases such as diphtheria, typhoid fever, and tuberculosis must be consolidated; and fresh and intensive attacks must be launched along new fronts.

I will refer briefly to a few of these new programs which have been close to my heart and have been made possible by the splendid coöperation of the Legislature.

I am reliably informed that 12,000 lives are sacrificed each year in New York State to the ravages of pneumonia. In January, 1936, I was happy to launch a state-wide campaign for pneumonia control—in which it was emphasized that although there are 32 types of pneumonia germs, Type I is by far the most common variety, and that the state was prepared to furnish a potent and reliable serum for its treatment. It had been shown that this serum could cut the number of Type I pneumonia deaths in half or even by two-thirds.

In the short period of 1½ years this demonstration, started jointly under private and public auspices, has shown the effectiveness of rapid and positive means of identifying pneumonia, and

has demonstrated that efficient antisera can be produced to combat certain of the more common types of the disease. I am informed by Dr. Godfrey that the use of Type I pneumonia serum produced by the State Department of Health has already saved many lives and has prevented serious, disabling complications in hundreds of others—thereby saving expense, suffering, and worry.

In the eyes of a progressive state these results made additional support for this life-saving program almost mandatory and, on April 24, 1937, I signed a legislative appropriation which made available to the State Department of Health, \$400,000 for use in "Furthering and Promoting the Efficient Prevention, Diagnosis, Treatment, and Control of Pneumonia." I am told that under this new appropriation it soon will be possible to provide sera for the treatment of more than half of our pneumonia cases and that subsequent research should bring the total to nearly 100 per cent.

In 1936, syphilis was responsible for 87,350 cases and 1,258 deaths, reported in New York State, including New York City, and stood first in the number of cases among all the reportable diseases and was exceeded in deaths only by pneumonia and tuberculosis. Yet syphilis is a preventable disease for which specific treatment has long been known.

An intensive state-wide syphilis control program was started more than 2 years ago with the aid of added appropriations made by the 1935 Legislature. These and subsequent state appropriations together with federal assistance under the Social Security Act have put New York State well on the way to meet the challenge made by Dr. Parran, in his recent book, *Shadow on the Land*, when he said: "In not a single state of this country have we

completely adequate free treatment even for the indigent."

Until very recently false modesty has interfered with a free discussion of syphilis. I am very glad to have had an active part in breaking the conspiracy of silence in New York State with regard to syphilis by public addresses on the subject and by my signature in May, 1937, of a law which changes the name of the Division of Social Hygiene in the State Department of Health to the "Division of Syphilis Control."

Early diagnosis and prompt treatment is productive of results not only in the treatment of communicable diseases such as tuberculosis, pneumonia, and syphilis, but also in the treatment of such a disease as cancer which was responsible for more than 19,000 deaths in New York State in 1936 of which almost half were in the state exclusive of New York City.

At a clinical congress of the American College of Surgeons some time ago it was stated: "If all the cases of cancer could be diagnosed early and treated promptly in their incipiency the annual number of deaths from this disease, now recorded as 150,000 in the United States and Canada, would be reduced by at least 33 per cent or 50,000 per year." In a special message to the Legislature on February 18 of this year I called attention to the lack of "available facilities for the treatment of those suffering with cancer . . . especially for those in the lower economic scale." I also said: "I am convinced that the people of this state do not wish these conditions to continue." This conviction on the part of both myself and the State Legislature with regard to cancer control has resulted in the appointment of a Temporary Cancer Commission and in an appropriation of \$510,000 for the purchase of a site and the erection of

a 100 bed cancer hospital to implement and make more available to the citizens of the state the treatment and research facilities of the State Institute for Malignant Diseases in the City of Buffalo. Comparable action for all of the states has since been taken by the Congress and President of the United States.

To call attention to this problem and the need for educating the public to call a physician in time, once again I propose to designate by official proclamation the first week of November as "Cancer Crusade Week."

As we emerge from the depression, we must all solidify the gains we have won with so much difficulty. Some modifications may well have to be made, but, by and large, the essentials of the economic, social, and health reforms we have achieved, should remain as permanent fixtures in our body politic. With a true sense of public responsibility uppermost in the minds of all our people, we will recognize that, although the years to come will require other new changes and new plans—together we shall press steadily onward in our March of Progress.

Records Handbook

THE National Organization for Public Health Nursing has published a new handbook on records entitled, "Suggestions for Statistical Reporting and Cost Computation in Public Health Nursing," which supersedes the one prepared in 1932 by a joint committee of that organization and the U. S. Children's Bureau.

There are two sections, the first on the statistical report of public health nursing services, and the other on computing the cost of a visit. The definitions, instructions, and tabulation forms in the first section conform with those approved by the State and Territorial Health Officers, the U. S. Public Health Service, and the U. S.

Children's Bureau in 1936, which are included in *Reprint No. 1768* from *Public Health Reports*. Also, the report form has been planned to make the data with reference to public health nursing service, required for the American Public Health Association Appraisal Forms, available.

The methods described for determining the cost of the nursing visit, while not applicable in their entirety to the nursing service rendered by public agencies, will be of interest to health departments contemplating studies of such cost.

The handbook can be ordered from the National Organization for Public Health Nursing, 50 West 50 Street, New York, N. Y., at 25¢ per copy.

The Familial Aggregation of Infectious Diseases*

WADE H. FROST, M.D., F.A.P.H.A.

*Professor of Epidemiology, School of Hygiene and Public Health,
Johns Hopkins University, Baltimore, Md.*

ONE of the most characteristic features in the epidemiology of the common acute communicable diseases is the grouping of cases in time and space; and this is especially apt to be noted in the group which constitutes a household, people in close contact with each other, sharing a common environment, mostly of close kinship, and usually under the eye of at least one medical or lay observer whose observation encompasses the whole group. It might be supposed, then, that we would have unusually full knowledge and exact records of intra-familial concentration of infectious diseases. And it is true that much of what we know about the communicability of certain diseases, and the special conditions related to exposure, susceptibility, and immunity is derived from observation on their spread—or failure to spread—in attacked families. It is also true that it has long been customary, even in rudimentary discussions of the epidemiology of communicable diseases, to give some account of the frequency and sequence of multiple cases within the family. But notwithstanding the tremendous mass of observations and literature bearing upon the concentra-

tion of communicable diseases within the household, our knowledge of the subject is still, for the most part, diffuse and unorganized.

This is due partly, perhaps chiefly, to the fact that the observations which have been reported have been presented in a variety of different forms, usually incomplete, and not readily convertible to a common basis. For instance, one observer will report the number or proportion of families in which more than 1 case occurred, while another will report the proportion of all cases in the community which occurred in families with more than 1 case. Both of these forms of statement are obviously incomplete, and neither is convertible into the other. A better, though less common, form of statement is the number of families having 1, 2, 3, . . . etc. cases; but this is of limited significance unless the material is further classified to show the distribution of families by size, and the presentation then becomes cumbrous.

Such systematic knowledge of the subject as we have today we owe largely to Dr. Charles V. Chapin, to whom we are indebted not only for furnishing the most extensive data as yet available on three communicable diseases—scarlet fever, diphtheria, and measles—but even more for having de-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

veloped and introduced the simplest, most direct, most widely applicable and useful method so far devised for assembling the essential facts. The development of this method is only a detail in Dr. Chapin's classic studies of the epidemiology of communicable diseases; but it is a detail which is so intimately related to the whole plan and purpose of his work, and has been so widely useful, that it has seemed to me of interest to follow his approach to this particular way of summarizing experience.

The method which Dr. Chapin used for quantitative description of familial aggregation, a method which, so far as I have been able to ascertain, was introduced by him,* is the so-called "secondary attack rate"; that is, the attack rate, within a specified time, in members of attacked families exclusive of the "primary" case, time being reckoned from the onset of this case. The method itself is familiar; but before discussing its history it may be appropriate to call attention to its special merits—simplicity, and adaptability to a variety of uses.

The facts required are simple. They are, essentially: the date of onset of the first case in each family; enumeration of the other persons present in the household at the time; and record of the dates of onset of such additional cases as occur among them within a specified time from onset (or recognition) of the first case. It is useful and customary to add further facts about the primary cases, their household associates, and the cases among them, in order that the secondary attack rate may be related to such circumstances as the character and man-

agement of the first case, the sex, age, and previous history of others in the household, various details of their habits, movements and environment, and perhaps their kinship to the primary case. In addition to being simple and readily obtainable with fair accuracy, these facts are all of the kind essential for guidance of administrative authorities in their management of cases of communicable diseases.

Given the essential facts, their compilation for derivation of secondary attack rates is equally simple. It is necessary only to set up an array of the exposed persons, that is, in each family, all those present exclusive of the primary case, classified by sex, age, or other conditions which it is desired to take into account; to set up parallel arrays of the cases occurring in each group within specified time limits dating from onset of the first case in each family; and to calculate the secondary attack rate as a simple ratio between cases and exposed persons in each class. It is, of course, necessary, in any particular study, to adopt certain definite rules which may have to be more or less arbitrary, or to follow established conventions, in such matters as the definition of a "primary" case, the period of time for which the secondary attack rate is to be calculated, etc. These, however, are merely the elaboration in detail of what is essentially an altogether simple procedure; and the same may be said of the devices which must be employed in application of the method to chronic diseases or to frequently recurring infections such as the common cold.

The secondary attack rate has the further merit that it yields information in terms which are simple and directly related to the practical problems of the health officer. The question or series of questions which it answers directly is: given a case of communicable disease in the family, what is the

* It is of course impossible to be certain that this method had not been used and presented in some earlier publication; but the evidence available to me indicates pretty clearly that Dr. Chapin devised the procedure to meet his own needs, and it is certain that its general use in this country derives from his work.

risk of attack borne by others in the same household within specified periods of time, and how does this risk vary with the character and management of the original case and with the sex, age, past history, and various other circumstances of those exposed? It is upon the answer to these questions that the health officer must base his decisions as to the kind and duration of protective and restrictive measures which are required for the protection of the family and the public.

In addition to its quite obvious usefulness in giving a direct answer to practical questions of this kind, the secondary attack rate has broader significance in contributing to better understanding of the natural history of communicable diseases, especially the directly transmitted endemic infections for which the human host is obligatory. For such diseases the secondary attack rate gives the best approximation we have to the limits of incidence of the clinically recognized disease—or equally of the sub-clinical infection where it can be independently observed—in a group subjected to almost certain physical exposure to the infective agent. More extended knowledge of these limits is of fundamental importance, not only for comparison of one disease with another, but equally for comparing the manifestations of the same disease in different areas and different periods of time.

It is also of interest to ascertain the ratio of the secondary familial attack rate to the currently prevailing attack rate of the same disease in the general population; and this is readily done because the two rates may readily be reduced to the same time basis and are otherwise directly comparable. The interpretation of this ratio is not simple, but it clearly is an index of the focalization of disease or infection around the recognized clinical case, and has interesting if somewhat elusive im-

plications with respect to the relative frequency of clinically manifest cases of the disease as compared with concealed carriers of infection at large in the community.

Those who have found the secondary attack rate ready-made, having become familiar with the procedure before they have encountered the problems to which it applies, are apt to think that because it is so simple and direct it must have suggested itself immediately in the study of infection in families. But in epidemiology, as in other fields, the procedures which are at the same time simplest and most efficient are not often the ones which suggest themselves first. The direct approach to any problem is only one of many possible approaches, most of which are indirect; and there is an adage which reminds us that the appropriate method is most likely to be invented when it is needed to achieve a definite result. This appears to be the history of Dr. Chapin's development of this particular method. So far as may be judged from the methods which he actually used in assembling his data, it appears that he first used this particular form of statement when his investigations had raised a quite definite and specific question which could be answered only in terms of the secondary attack rate.

The record from which this is inferred, fortunately an unusually full record, and the only one to which I shall refer, is the series of annual reports rendered by Dr. Chapin as Superintendent of Health of the City of Providence, R. I., beginning with the first year of his incumbency, 1884, and followed through 1905, beyond which, for present purposes, it is not necessary to go. In these reports Dr. Chapin gives and discusses, year by year, a series of tables presenting his observations on various aspects of the epidemiology of scarlet fever and

diphtheria. These, taken in sequence, give an objective record of the specific problems taken up and of the data and methods used in attacking them.

In the first paragraph of the first report of the series, for the year 1884, following a comment to the effect that health departments probably are devoting too large a share of their attention to the abatement of nuisances, Dr. Chapin expresses the belief that "there is no doubt that more attention might well be given to the prevention of the more common infectious diseases and more time devoted to their scientific investigation," and following this, he notes the need of a medical inspector for this purpose. The report for the next year announces the appointment of Dr. Gardner T. Swarts as Medical Inspector, and among his duties, listed in detail, specifies:

To visit every case of contagious disease which is reported to this office . . .

To obtain as much information in regard to the cause of the disease as possible and to keep a record of all cases on blanks which, when returned to this office, are there kept on file.

It is of interest that the report of the Medical Inspector for this year gives the following somewhat unusual table, which includes in one group cases of scarlet fever, diphtheria and typhoid fever:

Whole number of cases reported	387
Number of premises inspected	321
Extra number of cases on same premises	66

Beyond the suggestion which this table gives of a special interest in the spread of contagious disease within the family, there is little in the first three reports to indicate the particular lines of investigation to be pursued. These are revealed, however, in the report for 1887. Here Dr. Chapin mentions that he has "collected some facts in regard to cases of scarlet fever occurring during the latter part of last year,

which, perhaps, are not of much value in themselves but may be when the number of cases can be increased." This marks the beginning of systematic tabulations of certain facts about scarlet fever, continued in substantially the same form for more than 20 years, adding to the numbers each year. Dr. Chapin's discussion, in the 1887 report, of the data on scarlet fever collected that year, indicates pretty clearly the kind of facts collected and the specific questions which they were intended to answer. These, however, are indicated as clearly and somewhat more succinctly in the table given below which first appeared in the report for 1888 and was continued thereafter for many years in nearly the same form. For convenience of reference the table as reproduced here is divided into 5 numbered sections. There is no such subdivision in the original, but in all other respects the table is precisely as shown here.

Each section of the table states by implication at least one definite question having reference to the frequency of the extension of scarlet fever to other members of the same family, or to other families in the same dwelling. Excepting the last question, which refers to frequency of attack in (susceptible) *individuals* following return to their homes, the most direct answers which the data give to the questions are in terms of the proportion of *families* in which the extension occurs. The secondary attack rate in "susceptible children" (without further differentiation by age) may be derived very easily from the data given in section (1) of the table and would probably yield the most satisfactory answer to the general question there indicated. I think it will be granted, however, that given sufficiently extensive observation—which Dr. Chapin subsequently accumulated—all the specific questions proposed in the table

SUMMARY OF OBSERVATIONS ON SCARLET FEVER

*From the**Sixth Annual Report of the Superintendent of Health of the City of Providence for the Year Ending December 31, 1888*

(The table as printed is not divided into the numbered sections shown here.)

	1887	1888	Total
<i>1</i>			
Number of families in which there was more than one susceptible child	232	244	476
Number of these in which there was no second case	102	97	199
Number of susceptible children in all the above families	986	827	1,813
Number of these children who were attacked	452	511	963
<i>2</i>			
Number of additional families with susceptible children in the same house where the disease appeared	112	128	240
Number of susceptible children in these families	381	354	735
Number of these additional families attacked	27	16	43
Number of children in these families attacked	58	21	79
<i>3</i>			
Number of families where inunction was practiced	87	99	186
Number of instances in the above families where the disease was not confined to one case	44	64	108
Number of susceptible children in these families	218	496	714
Number of these children who were attacked	148	319	467
<i>4</i>			
Number of tenements which were fumigated	51	63	114
Number of instances where fumigation was done, and where the disease spread to other families in the house	5	5	10
<i>5</i>			
Number of instances where susceptible children were at once removed	24	18	42
Number of instances where they were attacked on their return	3	1	4

A susceptible child is defined as "one who has not had the disease"; and a footnote to the table explains that "two months is allowed to elapse before the family account is considered closed."

may be answered satisfactorily by analyses in the forms indicated. Use of the secondary attack rate would have been preferable in some of the analyses; but in none is it obligatory.

The same report, for 1888, gives, for the first time, in incomplete form, a table which, in various more complete forms, is continued thereafter for many years. It refers to attacked families, and shows, by single years of age, up to and including age 20 (all above this age being grouped together as adults):

(1) "Number exposed," *i.e.*, the whole number of persons of indicated age present in the families, including both primary and secondary cases

(2) "Number of cases," without distinction between primary and secondary

(3) "Ratio of cases to number exposed," expressed as a percentage

Inclusion of the primary cases among the number of "exposed" is unfortunate.* It makes the ratio of cases to people "exposed" exceedingly difficult to interpret, and in fact Dr. Chapin himself appears at times to

* The persons first attacked in their families have of course been "exposed" to the specific infection of scarlet fever; but, having come into the table *because* of having scarlet fever, they are not exposed to the risk of contracting it within the time to which the table refers. The failure to distinguish between these two meanings of "exposure" makes the table confusing.

have misinterpreted it. Nevertheless, this form of tabulation has a definite and useful place in the sequence leading to subsequent use of the secondary attack rate. It requires only dissection of the basic data to yield secondary attack rates; and, as it stands, it gives useful information as to age distribution.

Beginning in 1889, the reports include tabulations for diphtheria equivalent to those which have been mentioned for scarlet fever; and from 1896 separate tables are given for diphtheria in families where the diagnosis was bacteriologically confirmed.

In 1903 an important addition is made to the series, namely, a table relating to scarlet fever and a similar one for diphtheria, showing, for a considerable period of years, the number of secondary cases distributed according to time of onset in days from onset of the primary case in the family. The age distribution of secondary cases is not given in these tables.

It is in the report for 1903 that Dr. Chapin first makes use of the secondary attack rate. Since 1891 an increasing proportion of cases of diphtheria and scarlet fever had been removed each year to the hospital for contagious diseases; and the question which brings in the use of the secondary attack rate is that of the resultant benefit to other members of the families from which the primary cases had been removed. Referring first to diphtheria, Dr. Chapin gives a table showing, by age, the number of persons left at home in the families from which primary cases were removed to the hospital. Among the 1,420 persons included in this group, 55 were attacked subsequent to removal of the primary case. The specific question asked is: how many cases of diphtheria might have been expected in these 1,420 people if the primary cases had remained at home? This, as he notes, requires the calculation of age-specific secondary attack rates—i.e., attack rates in members of the family *exclusive* of the primary case—in families where the primary case remained at home. No table was available giving the full data required for calculating these rates, namely, (1) the age distribution of persons in attacked families *exclusive* of the primary cases, and (2) secondary cases at each age. However, a table (A), which has been mentioned heretofore, gives the aggregate number of secondary cases (1896–1903), not separated by age; and another (B) gives, in attacked families, the number of cases, and the ratio of cases to people. Referring to these two tables, Dr. Chapin observes that the secondary cases constitute about 40 per cent of all that occur, hence he takes 40 per cent of the ratios shown in table (B) as representing approximately the secondary attack rates. Applying these rates to the corresponding age groups of the population left at home, and making an ingenious adjustment for the varying intervals from onset of the primary case to removal from home, he estimates that had these patients remained at home their familial contacts might have been expected to suffer an incidence of about 120 cases instead of the 55 actually recorded. The same method is then applied in estimating the "expected" as contrasted with the observed incidence of diphtheria in well persons who removed from their homes subsequent to the onset of the primary cases; and similar estimates are made with respect to scarlet fever.

Two years later, in the report for 1905, appears the first table giving age-specific secondary attack rates for males, females, and both sexes combined. It refers to diphtheria, including only families for which the diagnosis was bacteriologically confirmed, and includes data for the full

decade 1896-1905. As the table is given here it is necessary to refer to another table for some basic data used in calculating the rates, but with this reference it is complete. Later, the form and arrangement of the table were altered at various times, bringing the data together in more convenient form. Beginning in 1908, tables are added showing secondary attack rates in scarlet fever; and in various subsequent reports special tables are given showing separately the secondary attack rates in families where the patient lived (that is, recovered) and remained at home; in families where the primary case was removed to a hospital, and in families employing servants or nurses. In general, these tables refer back to dates considerably earlier than the dates of the reports in which they first

appear, and the figures given are large.

This review has followed only one particular line of Dr. Chapin's studies, the one which led to use of the secondary familial attack rate. No attempt has been made to follow through the many other lines along which his investigations of scarlet fever and diphtheria extended; and space does not permit even their enumeration here. Most of the specific questions investigated did not require use of the secondary attack rate and had already been answered by other methods and in other terms before this form of statement had been adopted. When a specific question eventually arose definitely requiring this method, the essential data had already been provided, and the method itself cannot have been far below the surface.

National Foundation for Infantile Paralysis

FOLLOWING his recent announcement of the establishment of the National Foundation for Infantile Paralysis, President Roosevelt has issued a statement of the appointment of 34 citizens of various parts of the United States to serve as trustees.

It is hoped that a fund of from 7 to 10 million dollars will be raised in the next 5 years, with which the Foundation "will make every effort to ensure that every responsible research agency in this country is adequately financed to carry on investigations into the cause

of infantile paralysis and the methods by which it may be prevented. . . ." It also aims to develop means of enabling those already crippled by poliomyelitis to become economically independent in their own communities.

All funds collected through the celebration of the 5th annual "birthday ball," held January 29, 1938, in honor of the President's birthday January 30, will be given to the new Foundation, instead of being divided as heretofore between the Georgia Warm Springs Foundation and local communities.

A State Cancer Program^{*}

HENRY D. CHADWICK, M.D., F.A.P.H.A., AND
HERBERT L. LOMBARD, M.D., F.A.P.H.A.

*Commissioner of Public Health; and Director of Adult Hygiene,
State Department of Public Health, Boston, Mass.*

AN Act establishing the first permanent state board of health in the United States was signed in Massachusetts on June 21, 1869. The keynote of the fullest interpretation of the term "public health" was inherent in this first beginning and the beginnings from which it, in turn, sprang. This law mentioned the 4 important activities of health departments: (1) vital statistics, (2) communicable disease control, (3) epidemiology, (4) sanitation. The first chairman of the board, Dr. Henry I. Bowditch, began his first report¹ with his comprehensive concept of public health. In part he said:

No board of health, if it rightly perform its duty, can separate the physical from the moral and intellectual natures of man. These three qualities of man are really indissoluble, and mutually act and react upon each other. Any influence exerted to the injury of one, inevitably, though perhaps very indirectly, injures another. As in the physical world there is a correlation of forces, so that no force is ever lost, but only interchanged with another, so do these various powers and qualities of man act upon each other, and act and are acted on by the physical forces of nature that surround him.

By the careful and comprehensive study of these various laws and of their relations, the highest department of the physician's art is brought into operation. But no man or private body of men has the ability to study and to develop this department as a free commonwealth can do when acting through the agency of a few persons who are devoted to this object, and who come willingly to

the work, and armed with the power and the ample means of the state. Hence the term "State Medicine," though criticised by some, becomes a most appropriate and terse expression of the position which our Commonwealth has now assumed. . . . The State Board of Health . . . will adopt the fine old maxim, pagan though it be, that nothing which pertains to humanity, in its widest sense, will this board deem foreign to its aims.

This seemingly visionary prediction has been realized in the increased responsibilities which the Legislature has placed upon official public health.

Cancer was first mentioned officially by the Massachusetts Health Department in the annual report in 1896. A legislative decision to have the situation studied statistically resulted in 1900 in Whitney's classic report on cancer statistics.²

The only other official act of the Health Department until the inception of the program in 1925 (aside from yearly statistical mention and an occasional lecture) was the establishment of a tumor diagnostic service in 1919.

Independent groups led by physicians, clergymen, and others, began to take action, first in one part of the state and then in another, seeking assistance for the local cancer problem. Eventually, these several independent currents of interest blended into one broad common channel, and by 1921 the state-wide coöperation of a majority of the medical profession, together with the interested clergymen and lay-

^{*} Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

men, unique as far as can be ascertained, manifested itself: first, by stimulating an intensive study of the whole state cancer situation, with all its multiple variables and, second, by sweeping into law a program comprising the five salient recommendations of the study.

Thus, the cancer program came into existence with state-wide acclaim and enthusiasm. The real secret of its persistent popularity probably lies in the feeling on the part of so many individuals that they had a hand in its inception. It should be mentioned that some physicians, including the Commissioner of Health at that time, questioned its place in a health department. Their opinions were recorded, but were overruled by popular sentiment.

The early years of the cancer program witnessed the opening of the state cancer hospital at Pondville, the organization of 12 cancer clinics in the several parts of the state, educational work of a general type, and statistical research. At the beginning of any program, constant appraisal and revision is necessary before the most satisfactory working plan is evolved. After 8 years of operation under the original schedule, in 1934 the Commissioner met with an interested group and discussed a reorganization of the whole cancer program. The revised plan has been in effect for 3 years, and the results justify a belief in its effectiveness.

It is significant that the introduction of this program focused the attention of the department for the first time on chronic disease. This, however, was a logical development of health service. The great reduction in the morbidity and mortality from gastrointestinal diseases of infancy and childhood and the acute communicable diseases, and the aging of the population, have placed chronic disease in the forefront, taking

its toll of two-thirds of total deaths from all causes in Massachusetts. A department of public health must keep in step with these fundamental changes and readjust its activities to meet the problems incidental to an older population.

A state health department has the organization to bring together all the factors and factions that should be engaged in a cancer program to the end that continuity of effort and coöperation of patient, physician, and health official may be assured, and the resources of the state made available to wage a campaign against a disease that in Massachusetts is causing one-eighth of all deaths at the present time. As a cause of death, cancer has but one superior—the cardiovascular group.

The cancer program in Massachusetts has 5 main features:

1. A tumor diagnostic service
2. A state hospital for the treatment of cancer
3. Diagnostic clinics
4. Education of physicians and the laity regarding cancer
5. Statistical research for the evaluation of the problem.

TUMOR DIAGNOSTIC SERVICE

A tumor diagnostic service is maintained by the department in conjunction with the Harvard Cancer Commission. Any physician or hospital may have suspected tissue examined to determine the presence or absence of cancer.

STATE HOSPITAL FOR THE TREATMENT OF CANCER

The Pondville Hospital, with 145 beds, is maintained by the Commonwealth exclusively for the treatment of cancer. A new ward of 50 beds is nearly ready for occupancy at the Westfield State Sanatorium in the western part of the state. Patients with cancer or suspected cancer of all

types and stages may be admitted to these hospitals provided they have been in Massachusetts for 2 of the preceding 3 years and are certified for admission by licensed physicians. The charges for individuals able to pay are \$10.50 per week; all others are hospitalized at no expense to themselves. Hospital charges to cities and towns for patients unable to pay their own fees are \$2.50 per day. No additional charge is made for service or treatment. Diagnostic services are free in the out-patient clinic, while the charge for treatment is \$1.50. Diagnostic, surgical, therapeutic, radium, X-ray (diagnosis and treatment), medical, and nursing services are available. An out-patient clinic for diagnosis and treatment is held on Thursday afternoon for new patients at 1 p.m. and old patients at 2 p.m.

From the inception of the plan for hospital treatment, it was recognized that great care would have to be exercised to prevent the institution from becoming known as a "Death House" or a home for terminal cases. To avoid this it was decided that only patients would be received for treatment of conditions that were susceptible of relief or in which there was a hope of cure. No patients were excluded if their sufferings could be mitigated by any form of treatment or whose lives could be prolonged by operation or radiation.

The stay in the hospital was strictly limited to the time necessary to carry out the treatment, and then the patient was discharged to his home or to another institution. This wise policy has resulted in keeping the period of hospitalization to a minimum and making the beds available to as many patients as possible. The average stay for each patient is approximately 36 days and, therefore, each bed is made to serve 10 patients per year.

When patients are discharged they are instructed to return to their physi-

cian for follow-up, or if they have no physician, to return to the out-patient department of one of the state-aided cancer clinics at regular intervals. A well developed social service keeps in touch with the patient or physician to see that recommendations made by the hospital staff are carried out. The plan entails reports as to the patient's condition as long as he lives, and complete records of progress are kept at the hospital. Periodically, the members of the staff summarize the cases of different types of cancer and evaluate the results of treatment. By this follow-up system, the patient is kept under constant supervision and, if it is necessary, may be returned to the hospital for further treatment without delay. The judicious use of radiation and alleviatory operations has lessened the sufferings of a large number of patients thought to be incurable, and many of them have been able to return to their homes to carry on some of their daily duties.

At the beginning of the cancer program, the department and many physicians were apprehensive that the cancer cases that went to the state hospital would simply lower the attendance elsewhere. This has been proved to be a groundless fear. In 1935 the state cancer hospital admitted 1,186 cases. In the same year, 81 other hospitals, comprising about three-fourths of the total hospital beds in the state, admitted 5,488 cases. These same hospitals in 1925 admitted 3,585 cases. The actual number of cancer deaths increased in the period of 10 years by 25 per cent, but the hospital admissions for cancer, including the state cancer hospital, by 86 per cent. Apparently, the intensive cancer program has increased the attendance at the hospitals.

DIAGNOSTIC CLINICS

A method for providing adequate medical care by augmenting the re-

sources of the individual physician, rather than by supplanting the physician himself, has been tried in the Massachusetts Cancer Program. The cost of X-ray, radium, metabolism tests, cardiograms, and certain laboratory procedures is far in excess of the ability of the man of low income to pay. By furnishing such diagnostic procedures when needed, a form of socialized medicine is introduced which benefits both the physician and his patient and obviates more drastic change. It has been stated that every individual should not have medical care and treatment because every individual cannot afford it, but who is to determine which man's life is to be saved and which lost because of lack of money which, in itself, is often the result of an economic system over which the individual has no control.

In the Massachusetts Cancer Program the state furnishes a hospital and 20 clinics. Every physician in the Commonwealth may bring or send his patient to one of these clinics for free consultative service. If the case requires such a diagnostic procedure as extensive X-ray, this will be paid for by the patient if he is able and by funds available for this service if he is not. Each patient is referred to the physician who sent him to the clinic and the physician decides whether or not he desires further assistance in securing treatment for his patient. If he does, the state cancer hospital and the social service staff are at his disposal.

These 20 clinics are located strategically so that no person requiring an examination need travel more than 25 miles from home, at the most, to obtain it. These clinics are solely for diagnosis. The cancer clinics are administered by committees appointed by local medical organizations, which have charge of the administrative details connected with their respective clinics,

but in all cases they must conform with the minimum standards set by the department. These are:

1. Group diagnosis—The group must consist of at least 3 men, preferably surgeon, pathologist, and radiologist. When any of these are not available, other physicians may be substituted.

2. Uniform records—Forms are furnished by the department for this purpose as is also money for clerical service when needed.

3. Social service—All cases of cancer and precancer are referred to social service for follow-up. The follow-up continues until death in the case of cancer and until removal of the lesion in the case of precancer. The state either furnishes money to help defray the expenses of the social worker or furnishes the clinic the services of a part-time social worker.

The clinics must meet at least twice a month. At intervals determined by the clinic committee, but in no instance less than 4 times a year, some form of teaching for the physician in the community is required. Most clinics perform this service by having consultants come to the clinics at stated intervals, while others conduct teaching clinics by members of their own staff.

The clinic itself is furnished the following services by the state: (1) advice, information, and literature; (2) funds for or services of social worker; (3) funds for travel of social worker; (4) funds for X-ray diagnosis for those unable to pay; (5) funds for teaching clinics; (6) funds for clerical assistance in clinics; (7) funds for postage, telephone, stationery, etc.; (8) special clinics for the staffs of the clinics; (9) reference of cancer cases to Pondville through social service.

The purpose of the clinics is to furnish physicians and the public, group consultation service in cancer, as well as to improve the knowledge of cancer among the medical profession and the laity. The group furnishes a diagnosis and outlines a plan of treatment for any person suspected of having cancer, regardless of financial status. Every

effort is made to have the family physician either come with his patient to the clinic or send the patient with such information as he cares to furnish. Any individual is admitted to the clinic, although it is preferred to have the patients referred by physicians so that any tendency to use the cancer clinic in order to establish a diagnosis of a condition originally not suspected of being cancer may be eliminated.

As the success of treatment is largely dependent on early diagnosis, that phase of the program is stressed in all the educational activities directed toward the profession or the public.

That the present type of clinic organization is meeting with coöperation from the physicians is attested by the fact that in the first 2 years of the clinics physicians sent 51.4 per cent of all cancer patients to the clinics and in the last 2 years (8 years later) 77.3 per cent. The percentage of cancer patients coming to the clinics on their own account, that consulted a physician but were not advised by him to go to one of the clinics, decreased from 33.9 per cent to 11.6 per cent, while the percentage that consulted no physician has dropped from 14.7 to 8.3.

The cancer patients who come to the clinics on their own volition come earlier than formerly. In the first period they waited 12.3 months, in the last period 8.6 months, which shows that education through newspapers, radio, etc., has accomplished something, but the 8.6 months' delay in the last 2 years is considerably greater than the 6.9 months' delay of patients who consulted physicians before coming to the clinics.

By due consideration of these various factors, it would appear that the improvement found in cancer clinics is about 80 per cent due to the physicians' efforts, and 20 per cent to an improved public consciousness of the

disease. Although not satisfactory, this is far better than the reverse, for even if the public did not present itself at the cancer clinics until after the disease had been progressing for several months, it could be assured of much better treatment by the profession than it would have received 10 years ago.

RESEARCH

The studies have covered the volume of the problem; the existing hospital facilities in the state including the availability of radium and X-ray; the medical, social, and economic aspects of the disease; as well as such etiological findings as would be obtained by statistical analysis of death records, hospital records, and home visits to cancer patients. This work is continuing and reports are made on new evidence as it is acquired.

EDUCATION

The field of health education is at present in an elementary stage. For 30 years personal hygiene has been the subject of much popular discussion. On the whole, this has been based on fads and hearsay rather than on the results of scientific research. There are several experiments being conducted at present attempting to find a solution to this problem of disseminating knowledge. Scientific medicine is years ahead of its popular application. The problem is to present it in such a way that the individual will act upon the knowledge he receives. The backwardness in applying knowledge may be the result of an unfortunate tendency to talk generalities on the assumption that real knowledge is over the heads of the general public. If a disease and the present state of knowledge concerning it are explained in a clear way, the public responds with understanding and intelligence.

The reception of the Coöperative

Cancer Control Program in Massachusetts is the best and most recent example of this. If exact knowledge were discussed about cancer and the specific resources available were made known, the present percentage of cures would be nearly tripled in this state of more than 350 communities with a population of nearly 4,500,000, and over 7,000 physicians. Each town and city in the Commonwealth has been or is being organized into a small Coöperative Cancer Control Committee for the dissemination of this exact knowledge. Already 220 Coöperative Cancer Control Committees have been organized with results beyond any expectations. Every club, or even every small group of individuals which meets regularly, is asked to have a meeting on cancer once a year. The local physician is asked to meet with this group and discuss cancer and answer questions. This is the crux of the whole plan. At these small group meetings the public is informed of the relationship of chronic irritation to cancer, of the percentage of cures of the disease, of the fallacy of the cancer folklore, and the danger of the cancer quack. All physicians are participating in this program by giving these talks and answering questions. By teaching in this way, many practitioners are acquiring a better personal knowledge.

Another reason for the success of this plan is that it includes every group in the Commonwealth. The social, fraternal, racial, religious, military, political, and service groups are all represented. This is more than a cross-section. It is the whole population of the state. The influx of patients to physician and clinic following meetings of this sort shows that the information is being not only disseminated but acted upon.

The results of this method of education are already apparent. In 1936

the interval of delay between the first recognizable symptoms of cancer and first consultation with a physician showed, in Massachusetts, a decrease of nearly 20 per cent. For 9 years prior to this, the interval had remained practically stationary.

If the 12 months of 1937 show the same tendency that the first 6 months have shown, this period of delay will be even less. There has been a big increase in attendance of cancer patients at 2 non-state-aided cancer clinics in Boston in 1937 which the authorities attribute, in both cases, directly to the state educational program.

In 1934 Bigelow and Lombard³ published a paper showing that the cancer death rate increased for both sexes between 1900 and 1920, and that following 1920 there was no increase among females when allowances had been made for the changing age composition of the population. The table shown in this paper has been continued to include 1936. The years 1935 and 1936 showed a decline among females, with the rate in 1936 slightly lower than in 1935. The figure for the early part of 1937 points toward a continuation of this decline. This is particularly gratifying as it is another confirmation that the new program inaugurated in 1934 is producing tangible results. The male rate also may be responding to the program, although the evidence is not sufficiently marked to warrant any conclusions. Females have a greater number of accessible cancers and any improvement would be expected to show first in this group.

The effectiveness of the new cancer program is again demonstrated in the change in age at time of death. At the beginning of the program this was 63.3 years. In 1934 it had not improved, but in 1936 this figure had risen to 64.6 years. This indicates that lives are being prolonged as well as saved.

TABLE I

*Massachusetts Age, Sex Adjusted Cancer
Death Rates*

*Adjusted to Massachusetts 1900 Population
Rate per 100,000*

<i>Year</i>	<i>Male</i>	<i>Female</i>	<i>Total</i>
1900	50.2	91.6	71.5
1901	50.6	93.7	72.7
1902	47.9	97.0	73.0
1903	50.9	97.8	75.0
1904	54.2	102.9	79.2
1905	55.5	103.7	80.3
1906	63.1	99.5	81.8
1907	58.9	108.7	84.4
1908	59.9	108.7	84.9
1909	60.3	108.5	85.0
1910	63.7	111.3	88.1
1911	68.8	112.1	91.0
1912	63.5	117.6	91.3
1913	71.5	119.7	96.2
1914	70.9	119.6	95.9
1915	73.7	119.5	97.2
1916	77.1	126.5	102.5
1917	76.2	127.0	102.3
1918	78.6	123.2	101.5
1919	77.9	120.5	99.7
1920	84.5	128.6	107.1
1921	85.9	129.4	108.2
1922	83.5	126.9	105.8
1923	85.4	125.8	106.1
1924	92.2	127.5	110.3
1925	89.6	130.0	110.4
1926	94.3	127.5	111.4
1927	92.5	128.9	111.1
1928	94.3	128.8	112.0
1929	93.3	127.4	110.8
1930	96.8	125.4	111.5
1931	93.5	126.2	110.3
1932	96.7	129.2	113.4
1933	101.5	128.7	115.5
1934	107.2	129.4	118.6
1935	99.2	125.2	112.5
1936	105.9	124.9	115.7

The physician is the key man in the Massachusetts Cancer Program. The whole program revolves around him, and both he and his patients are helped. In this way, his traditional position is unimpaired and the close relationship continues to exist between patient and physician. The majority of citizens in this country prefer to retain their own family physicians. On the other hand, they need services oftentimes involving expensive procedures beyond their reach financially. Any plan, to be successful, must try to meet the needs of these countless thousands for adequate medical care. The method to be adopted will have to be planned to make the burden on the taxpayer as light as possible. The Massachusetts Cancer Program is enthusiastically supported by both physicians and the public and for this one disease is meeting the needs of the people as they have never been met before.

Diabetes—An Important Public Health Problem*

CHARLES F. BOLDUAN, M.D., F.A.P.H.A.

Department of Health, New York, N. Y.

BECAUSE of the marked decline in the birth rate, due to birth control and to the cessation of overseas immigration, there has been a steady aging of our population. This has brought with it an increasing mortality of diseases associated with the higher ages, such as chronic disease of the heart, arteries and kidneys, cancer and diabetes.

As health administrators, we naturally study these conditions in the hope that we may find some means of preventing them, or failing which some means of prolonging life.

The work of Allen on the treatment of diabetes and especially the discovery of insulin by Banting and Best, in 1921, attracted wide attention to diabetes as a disease in which life could undoubtedly be greatly prolonged. But even then, health administrators appear not to have regarded diabetes as a condition toward whose control they should provide in their health program. Here and there writers called attention to the steady rise in the death rate of diabetes, and the suggestion was repeatedly made that it was the result of the rapidly increasing consumption of sugar.

In 1929 I began to devote special attention to the statistics of diabetes, and urged consideration of this disease

as a public health problem. At first I too accepted the available statistics at their face value, but further study showed that this was misleading. I believe it will be helpful to review briefly the data which recent years have made available.

Because of the relatively uniform classification of New York City's mortality statistics over a long time, and because of the large population from which these statistics are drawn, I shall confine the discussion largely to conditions in New York City.

Taking the figures at their face value we appear to have a picture of diabetes mortality in New York City as shown in Table I.

Two features of this table deserve attention. First, note the rise in the death rate, from 2 per 100,000 in 1871-1875 to 30 in 1931-1935. Inasmuch as we know that prior to the introduction of insulin the case fatality of diabetes was high, the low mortality rates recorded in the earlier years would *seem* to indicate a very low prevalence of diabetes in New York City. The second point is the much greater rise in the mortality rate among females. During the earlier years, up to about 1900, the rates are approximately the same in the two sexes. Since then the diabetes mortality rate in females has risen much more rapidly than that in males, so that now it is more than double the male rate.

* Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

Why the rise in the mortality charged to diabetes? Why the approximately equal rates up to about 1900? What factor could have entered at that time to bring about so marked an increase in the death rate among females?

These are not academic questions and satisfactory answers are necessary in order that we may deal intelligently with diabetes as a public health problem.

The low mortality rates of the early years *seem* to indicate that there was far less diabetes then than there is now. But—

Was diabetes a rare disease? All the older medical textbooks speak of it as such. I am certain that this view is incorrect and that diabetes was very much more prevalent than the medical profession realized. The diagnosis of diabetes depends on the detection of sugar in the urine. Prior to 1850 this detection was largely by finding that the urine had a sweet, honey-like taste. Do you wonder that one of the textbooks says that it is a rather disagreeable test to make! Shortly before 1850 the Trommer and the Fehling chemical tests were introduced and are mentioned in textbooks published in the 60's and 70's. My study of the medical histories of New York Hospital

shows that it was decades before these simple tests were routinely applied. If this was true of a first-class hospital, how frequently is it likely were tests of urine for sugar employed by private physicians? Even today how often is such an examination a regular routine for all cases? Let us start, then, by holding that diabetes was by no means a rare disease and that it was simply not diagnosed.

The sex distribution as shown in mortality statistics—All students of diabetes are agreed that diabetes is more prevalent among females than among males. Why do the earlier statistics show about equal mortality rates in the two sexes? A simple and wholly satisfactory answer to this is furnished by the manner in which a large proportion of the cases of diabetes were discovered during those earlier years, namely, purely by chance as the result of examinations for life insurance. Fifty or 60 years ago the proportion of women applying for life insurance was small. Hence, what cases of diabetes were detected through such insurance examinations were almost all among men. Even though diabetes was then, as now, more prevalent among females, its detection in those years was more likely among

males. Hence the nearly equal mortality rates in the sexes.

This view also affords a reasonable explanation for the mounting excess of the diabetes death rate among females during the past 30 or 40 years. Inquiries of a number of large life insurance companies revealed a marked increase in the proportion of applications for life insurance from females. Increases amounting to 20 per cent or more since 1900 were reported.

Increase in the diabetes mortality rate since 1900—Our mortality statistics indicate an increase in diabetes mortality in both sexes during the past 35 years. A very large proportion of this undoubtedly represents only a more frequent recognition of the disease, especially among females. Besides this, an increase now amounting to at least one-third over the 1900 rates is due to the aging of the population. In New York City, for example, the proportion of the "45 years and over" group is more than one-third greater than it was in 1900. This is the age group which has by far the greatest proportion of diabetics. In New York City another fact must be considered, namely, the increase in the proportion of Jews in the population during the past 40 years. Diabetes appears to be from 50 to 75 per cent more prevalent among Jews than among non-Jews. In New York City, therefore, the marked increase in the proportion of Jews has also been a factor in the rising mortality of diabetes.

It is certainly highly significant that when due allowance is made for the aging of the population and the increasing proportion of Jews, the diabetes mortality rate in New York City among males shows a downward trend during recent years. If the explanations here advanced for the rising death rate among females are correct, we may expect the increase in females to con-

tinue for some time until the rate becomes stabilized at a point which represents approximately the relative prevalence of diabetes in the sexes.

I have dwelt so much on these statistical aspects of diabetes because their appreciation is necessary in order to keep us from following false trails. I am convinced that those who explain what they regard as a marked rise in diabetes mortality, are attempting to explain something which is not a fact. Bear in mind that I admit a *real* increase in the prevalence of diabetes because of the aging population. Beyond this, however, the increase indicated by the registered mortality is fictitious.

A number of writers, who apparently regard most of the increase in the recorded death rate of diabetes as real, see an explanation in a decrease in physical labor because of labor-saving machinery, and an increase in the prevalence of obesity. Among the arguments advanced, mention is made of the lower diabetes mortality rates among rural and urban populations, it being pointed out that there is generally more physical labor among the rural dwellers and that their diabetes death rates are distinctly lower. I believe that the chief and perhaps the only reason for the lower diabetes rates in rural populations is the greater extent of the medical services in urban areas, and that it is again a question of recognition. I also consider it far-fetched to conclude, because *recorded* diabetes mortality rates are higher among farm owners than among farm laborers, that the difference is due to the lesser amount of physical labor among farm owners. Surely farm owners, as a group, enjoy much better medical service than do the farm laborers. Finally, what evidence is there that there has been an increase in the prevalence of obesity, a statement often

made as though it were an established fact? I have attempted to obtain information as to the prevalence of obesity a generation ago and now, by personal interviews with, and data secured from manufacturers of shirts and collars, large clothing manufacturers, and makers of women's clothing. All those interviewed had quite definite opinions that there had been no increase in the prevalence of obesity. Unfortunately, in no case was it possible to secure actual figures over a sufficiently long period to make comparisons. In this connection, bear in mind that the mortality statistics seem to indicate an increase in diabetes limited to women. What facts support the alleged increased prevalence of obesity in women? Have not just the past 20 or 30 years been characterized by the vogue of the slim, boyish figure? Were slimming treatments ever before so popular as during the past quarter century?

Most experienced clinicians agree that there is a relationship between obesity and the development of diabetes. From what I have said, however, it should be clear that an alleged but improbable increased prevalence of obesity cannot be advanced to explain the rise in diabetes mortality. In males, having in mind the aging population, there is, I believe, no increase to explain; in females, present rates one-third higher than in 1900, are satisfactorily accounted for by the aging population, and increases beyond this are much better explained by increased recognition of the disease in women.

Prevalence of diabetes—Inasmuch as diabetes is not a reportable disease, we have no ready means of determining its prevalence. This difficulty is increased by the fact that many cases are unrecognized. Thus, even in a city like New York, where medical facilities are abundant, a survey conducted a

few years ago by the Academy of Medicine, embracing 1,600 cases of diabetes in 24 large hospitals, disclosed that in over one-sixth of the cases the diagnosis of diabetes had not been made before admission of the patient to the hospital.

A survey of chronic illness conducted in Massachusetts several years ago indicated that there were some 15,000 diabetics in that state. Joslin states that in 97 per cent of these individuals the condition had been diagnosed by physicians. This very high percentage leads one to believe that the total number of diabetics was substantially larger than that calculated from the survey findings, for, as just mentioned, the disease often remains long unrecognized.

Examinations of the urine of a large random sample of the general population would give valuable information as to the prevalence of diabetes. To be of value one would require the sample to consist of a sufficiently large number, male and female, in each of the important age groups. Thus far, so far as I know no such survey has been made, for it is an enormous undertaking. I made an attempt along this line some years ago, securing information regarding the percentage of persons with definite glycosuria among the new admissions to state hospitals for mental disease. The data were obtained from these hospitals because I knew of no correlation between mental disease and diabetes. Data from general hospital services would necessarily have included individuals who were admitted because of a diabetic condition. My survey embraced a total of only 3,685 persons, a number too small to yield more than a suggestion as to the prevalence of diabetes in the city's population. The percentages obtained in this study indicated that in New York City there might be as many as 100,000 diabetics.

That this approximate figure may

not be far from the facts, appears from the studies made by the New York Diabetes Association. These indicated that in one year there were about 8,000 patients attending diabetes clinics, and over 7,000 patients treated, as bed patients, in hospitals. A questionnaire sent out by the Health Department to all the physicians in the city elicited replies from 4,000 physicians who, altogether, were caring for 8,000 private patients having diabetes. This ratio of 2 diabetics for 1 physician may not hold for all the 15,000 registered physicians, but the number of private diabetic patients must run into the thousands. Besides the patients thus estimated, there is a considerable number of diabetics who are entirely unaware of their disease and therefore not under treatment, and also some who are treating themselves with patent nostrums. There is reason to believe that the total number of diabetics in New York City is not far from 1 per cent of the population, and it is probably conservative to estimate the diabetics in the United States as over 600,000. In any event the number is so large that the condition deserves wide attention as an important health problem.

Causative factors—Priscilla White and her associates have brought forward considerable evidence that heredity is an important factor in diabetes. Joslin emphasizes the rôle of obesity in the development of the disease in those with a diabetic ancestry. Mosenthal feels that pregnancy is often an exciting factor in the development of diabetes, citing my New York City figures which show nearly treble the diabetes death rate among married and widowed women over 45 years of age than among single women of the same age. Recent investigations disclose the important part played by endocrine disturbances in the development of diabetes. With all this newer knowledge

medical science has not yet unraveled the ultimate cause of diabetes.

Despite this ignorance as to the cause of diabetes there is much that can and should be done in dealing with diabetes as a health problem, for experience has shown that with the aid of insulin the lives of diabetics can be greatly prolonged. Many diabetics are now enabled to live out a normal life span, and do this while attending to their daily affairs like normal, non-diabetic individuals. To achieve this for as large a number of diabetics as possible should be the goal of our efforts. How shall we bring this about?

A practicable program—While the health authorities may well take the lead, they will need to enlist the coöperation of the medical profession, the hospitals and clinics, and the welfare agencies. Inasmuch as New York City was the first to organize an attack on diabetes as a public health problem, let me give a brief sketch of our work.

In 1932, at the request of Dr. Shirley W. Wynne, at that time Commissioner of Health, the New York Academy of Medicine appointed a special committee to study the problem of diabetes and make recommendations for dealing with the situation. The report of this committee, presented by the chairman, Dr. H. O. Mosenthal as the Hermann M. Biggs Memorial lecture in 1933, suggested the formation of a committee or association with a paid secretary, suitable office facilities, and a modest budget for necessary expenses. The functions of the proposed organization were enumerated as follows:

To act as a clearing house for the study of diabetes as a health problem, and to devise measures for the control of this disease.

To assist in the formation of a committee of clinics dealing with diabetes.

To stimulate more effective coöperation between clinics and hospitals in the treatment of diabetes.

To develop more extensive and more continuous graduate courses of instruction for physicians.

To carry on health education of the public in all matters pertaining to diabetes.

To assist in the preparation of exhibit material which can be used in the instruction of diabetics attending clinics.

To attempt a solution of the problem of providing insulin to the indigent.

To study the needs of the various parts of the city to the end that adequate facilities for diagnosis and treatment may be generally available.

To extend our knowledge of diabetes by the interchange of views at suitable meetings.

To train groups of nurses, as so usefully done by Joslin, in the special nursing of diabetics.

In New York, thanks to financial support provided by Lucius N. Littauer, this program was put into effect by the organization of the New York Diabetes Association in 1934. The work has been very successful and has led several other cities to organize programs along similar lines.

Today, with the chronic diseases of later life steadily assuming greater importance as health problems, diabetes deserves special attention. In none of the other diseases in this category have we such certain prospects of success in helping the victims live out a normal life span.

Pneumonia Service in New York

JOHN L. Rice, M.D., Commissioner, reporting on the first week's activities of the New York City Health Department's pneumonia service, stated that 69 specimens had been typed and 665 vials of serum supplied.

Plans are now being perfected by the Department of Health in coöperation

with the Pneumonia Advisory Committee to conduct refresher courses for physicians in the serum treatment of pneumonia. Such courses will be conducted in hospitals in each of the boroughs. In the near future the days, hours and location of the courses will be announced to the medical profession.

Allocation of Deaths

A PAPER by Miss Elizabeth Parkhurst, senior statistician, State Department of Health, Albany, New York, U. S. A., printed in the *American Journal of Public Health* (July, 1937), raises afresh the question of the allocation of deaths of citizens outside the area of their residence. In Britain we have had for many years a fixed convention that every death, whatever its cause or nature, shall be accredited to the usual place of residence of the deceased, whatever may be the length of time which has elapsed since the deceased left his native town. Residence is the place where the deceased had his home and to which he would be expected to return should he return at all. This system has several disadvantages and some absurdities, but it has the immense advantage of being definite; so we all know where we are, even if we find ourselves in an uncomfortable or incongruous position. In the United States there is no federal allocation of deaths and the various States have either no system of allocation at all, or local and various systems, all differing from ours. Miss Parkhurst, in her paper, pleads for a system more logical than ours, but in avoiding some of our difficulties, it introduces others which, though rather less incongruous, appear to us more formidable obstructions to smooth working. . . .

Everybody agrees that some method of allocation is essential everywhere, but it is most necessary in the States where more people die in institutions than they do here, and where many institutions are outside the districts they serve. The Americans tell a story of a small town in which the number

of deaths from typhoid exceeded the entire population. The American ideal that deaths should be allocated to the districts in which the cause of death operated is higher and more logical than ours and seems not much more difficult to reduce to practice. It is an absurdity that if the women of a small village go to a maternity home in a neighboring town and die there from an outbreak of puerperal fever, the village, which was innocent, should be saddled with a high maternal mortality rate. Or, if the people of the same village go for a joy ride and meet with disaster, that their deaths should be laid on the village from which they set out. On the other hand, how are we to allocate the death of a person from dysentery who has long been resident in a mental hospital? Britain being a small and compact country with a central executive and a uniform health code, the absurdities of our system of registration are theoretical rather than real, for we have ready means of detecting them. In the United States, with its vast area and different population distribution, its division into semi-autonomous States with different health codes, it is not easy to check these absurdities; so we can understand why the Americans look upon our system as too faulty for their adoption. Miss Elizabeth Parkhurst's proposal is to adopt our system except that deaths from acute communicable disease occurring in institutions should not be referred to the place of former residence. This has been advocated by many British hygienists, but it is replete with difficulties. — *Medical Officer* (London), LVIII, 14 (Oct. 2), 1937.

Determining Population in Intercensal and Postcensal Years by Means of Continuous Population Registers*

DOROTHY SWAINE THOMAS, PH.D.

Director of Research in Social Statistics, Institute of Human Relations, Yale University, New Haven, Conn.

THE resident population of a given area at any point of time after a census enumeration can be determined by adding or subtracting the net change in numbers since the last enumeration. This net change is obviously a function of the number of persons entering and departing from the area. Entrance to a resident population group occurs when children are born to residents or when persons migrate into the area and establish residence. Departure occurs when residents die or migrate out of the area. The determination of net change from the last census enumeration to any specified point of time requires the drawing of a balance sheet for the interval, indicating on the positive side, the number of births to residents and the number of persons migrating into the area, and on the negative side, the number of residents dying and the number migrating out of the area.

The theoretical requirement for such a balance sheet is continuous registration, not only of births and deaths at the time of their occurrence and with proper allocation to the residence area, but also of all persons establishing and

giving up residence in this area. This requirement is met by the continuous system of population registers, now existing in Sweden, The Netherlands, and certain other European countries. The principles of registration in Sweden and The Netherlands are the same, although they differ in regard to details. The Swedish system has the following features:

1. The smallest local administrative unit, the parish or the community, is the unit for population registration.

2. The pastors of the State Church (functioning, however, as civil servants) are responsible for keeping the registers.

3. The basic register is a so-called community book which is revised after each decennial census. In this book data are arranged in terms of household groups, indicating for each resident his family and given names, sex, relationship to the head of the family, birth place and birth date, civil status at the time of inscription, religious affiliation, nationality and citizenship, occupation at inscription, address in the community and place of previous residence, if an in-migrant from another Swedish community or an immigrant from a foreign country.

4. Changes affecting civil status or citizenship are recorded for those who

* Read at Joint Session of the American Statistical Association and the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

continue as residents. A new entry, containing all the above details, is made for every child born to a resident woman and for all in-migrants or immigrants. Removal of the name from the register occurs upon emigration, out-migration, death or "disappearance," with an indication for out-migrants of the community of declared destination, and the date of the receipt of an attested inscription in the community declared as destination, or some other community.

5. Although registration is in terms of individuals, the household or family unit is preserved, and appropriate changes are made as the individual shifts from one household or family group to another within the community.

6. These registers represent the current resident population. Abstracts relating to all new inscriptions and removals are made in a series of books referring to births, deaths, and migrants, and summaries of these are prepared every year. Demographic occurrences affecting the factual but not the resident population are not recorded in the main community register, but appropriate notations are made in the birth register or death register, and a transcript is sent to the community of residence.

7. Residence is determined by fixed rules and definitions, depending initially upon the intention of the individual concerned, but revised in situations where intention does not correspond with fact. No one may be registered as a resident of more than one community at a time.

8. Every person intending to change his residence to another community is required to take out a migration certificate. A transcript of the demographic history and status of this person is sent to the community of destination, but his name is not removed from the register of the community of origin

until a receipt attesting in-migration has been received from the community of destination. This is the so-called "closed" system of population registration: theoretically, no out-migration occurs except in connection with a subsequent in-migration. This rule is obviously applicable only to internal migrants.

9. Since civil rights, duties, and benefits are determined on the basis of registration as a resident, a person who evades registration is considered to have no such rights or benefits. An annual check of the registers, in connection with tax declarations, always reveals a certain number of persons who have disappeared from the community without taking out migration certificates, or who, after taking out certificates, and leaving the community, have failed to register elsewhere. Such persons are kept in the community registers for two consecutive years, but if their destination is still unknown at the expiration of the second year, they are declared to be statistically "non-existent" (*obefintliga*), are removed from the main register and are relegated to a special "Register of the Non-Existent" from which, in turn, they are removed only upon an attested in-migration or death in another community or upon return to the community in question.

10. Although registration is decentralized, control is centralized. Central registers are kept for persons having no defined local residence but considered nevertheless as residents of the country.

The Dutch system is, in principle, the same, but differs in the details of administration, personnel, and the technic of bookkeeping. The two fundamental points of difference from the Swedish system, are, first, that the registers are kept by civil officers, and second, and more important, that a

new "Family-Individual-Card" system has recently been introduced, whereby the card made out for each individual upon birth or immigration to the country is sent by post to the various communities of destination within the country, and thus contains a cumulative record of the individual's demographic experiences, which are recorded as they occur until his emigration or death, when the card is deposited in the Central Statistical Bureau. As providing a basis for determining the population in any administrative unit in intercensal or postcensal years, however, the system operates precisely as the Swedish, and a description of its details is not relevant to this paper.¹

The essential features of continuous population registration common to the systems in Sweden and The Netherlands are: (1) there is a basic record of all residents determined at a census enumeration; (2) this basic record is subject to continuous revision by additions, subtractions, or modifications as changes occasioned by birth, death, marriage, dissolution of marriage, adoption, migration, and disappearance, occur; (3) there is a set of specific rules for determining residence; (4) the system is "closed" with respect to internal migration; and (5) civil rights, duties, and benefits are linked with registration.

The usefulness of the continuous register system in determining intercensal or postcensal population obviously depends upon the completeness and the promptness with which births, deaths, and migrants are registered. There seems to be very little doubt that both The Netherlands and Sweden maintain excellent control of the registration of births and deaths. In Sweden, the allocation of births to the community of residence of the mother is insured by a requirement that women entering maternity hospitals present their certificates of registration. The requirement of allocations to residence community however evidently causes some delays in completing the registration, and this situation tends toward an underestimate of population increase, for births outside the community, which should have been entered in the registers undoubtedly overbalance deaths of persons who should have been removed from the registers. Thus, even though omissions may be and probably are negligible in the long run, they may play a not unimportant rôle at any given point of time.

Control of migration registration presents greater difficulties than control of vital registration. It is particularly difficult to obtain a complete record of all emigrants from the country, since the "closed" system of registration can obviously not apply to

TABLE I
Internal Migrants

	Sweden ²			The Netherlands ³		
	<i>In</i>	<i>Out</i>	<i>In-Out</i>	<i>In</i>	<i>Out</i>	<i>In-Out</i>
1929	482,705	480,206	+2,499	488,781	489,421	-640
1930	526,166	523,674	+2,492	509,175	509,380	-205
1931	477,388	475,470	+1,918	439,843	442,167	-2,324

1933	463,270	460,927	+2,343	414,877	415,196	-319
1934	471,704	469,221	+2,483	431,187	430,822	+365

(Average annual population, for these years, Sweden, about 6,180,000. Average population increase about 22,600.

Average population, The Netherlands, about 8,170,000. Average population increase about 115,000.)

emigrants. If the closed system were absolutely efficient in respect to internal migrants, the sum of the in-migrants, for the country as a whole, should equal the sum of the out-migrants, since, in theory, no out-migration can occur until an in-migration has been attested. Table I of in- and out-migrants for Sweden and The Netherlands in recent years shows the extent to which practice deviates from theory:

In Sweden the error is relatively constant and is always in the same direction, *i.e.*, a deficiency of out-registrations. If in-registrations could be taken as correct, under-registration of out-migrants would amount to about one-half of 1 per cent. In The Netherlands the differences have been proportionately less, reaching the Swedish level in only one of the years considered. The error is, generally, in the opposite direction, *i.e.*, an under-registration of in-migrants. It is impossible to know, however, the extent to which concealed compensating errors affect the total discrepancy, for two situations operate to produce the discrepancy: (1) The population registrar in the communities of destination may have neglected to notify the communities of origin that they have registered an in-migration, or the registrars in the community of origin may have neglected to delete an entry after receiving this notification. This will result in a deficiency of *out-migrants compared with in-migrants*.

(2) Migrants who intended to seek a destination within the country, and took out migration certificates may have changed their minds and emigrated from the country. If the registrar in the community of origin has, nevertheless, recorded these cases as out-migrants, this will result in a deficiency of *in-migrants compared with out-migrants*.⁴

Thus, the total error may be considerably larger than the apparent discrepancy, due to a compensating factor. These errors are, however, of the sort that can be diminished by improved administration of the closed feature of the registration system.

Even if the closed system operated with perfect efficiency, and practice of the registrars conformed with theory to the extent that every registered in-migration had its corresponding registered out-migration, there might still be a considerable degree of under-representation of migration, due to the failure of some migrants to apply for registration certificates. Both the Swedish and the Dutch systems attempt a correction of this error by periodic checks of the registers. In so far as the decennial census is complete, the cumulative errors are eliminated after each census, and the annual checks remove as many as possible, but always with a time lag, for "disappearance" is determined only after a specified absence (in Sweden, 2 years) from the

community. Table II shows the annual removal from and reentries into the registers for the period 1929-1934.

The net effect of these entries and removals is not constant either in amount or direction. The census year 1930 shows the largest absolute figures for both entries and removals and in both countries. In addition to the relatively large correction of the registers at census years, the Swedish series over a longer period show that the fluctuations in the net figure are inversely related to the phases of the business cycle: it is an advantage to be registered as a resident during periods of depression, in order to obtain relief; it is an equal advantage to avoid registration during periods of prosperity in order to evade taxation! Furthermore, the effect of under-registration may operate differently with respect to rural and urban areas, for it is probable that the population in areas of maximum in-migration (*i.e.*, urban places) will be slightly underestimated in intercensal and postcensal periods, and the population in areas of maximum out-migration (*i.e.*, rural places) will be slightly overestimated.

The limitations of continuous population registers as sources for deter-

mining intercensal or postcensal population may be summarized as follows:

1. Errors in respect to births and deaths will depend upon the factor of delay in reporting extra-residential births and deaths to the residence areas. These errors will be relatively constant, and will result in a slight underestimation, particularly of rural areas which have no large maternity hospitals.
2. Errors due to under-registration of migrants will operate as follows:

(a) A certain number of emigrants will escape registration entirely. This will cause a temporary overestimation of the population of areas of emigration.

(b) Out-migrants (internal) may evade registration and this may cause temporary underestimation or overestimation of the population of the area affected. These errors are not constant and probably vary inversely with the business cycle, and probably also have a differential effect as between rural and urban areas, tending in general toward an overestimation of the former and an underestimation of the latter.

3. Errors due to incomplete registration of internal migrants will generally operate in

CHART I

SWEDEN: AGRICULTURAL POPULATION IN BLEKINGE, KRISTIANSTAD AND MALMÖHUS COUNTIES

CHART II

SWEDEN: TOWN POPULATION IN BLEKINGE, KRISTIANSTAD AND MALMÖHUS COUNTIES.

the direction of an excess of in-migrants compared with out-migrants since these errors will be due to failure to maintain the closed system. The population of communities with inefficient removal of out-migrants from the registers will tend to be overestimated.

The net effect of all these errors will not be large if population registration is carefully controlled. The situation in The Netherlands and Sweden is favorable to such control, and it is possible that they have reached an

irreducible minimum of errors. In Sweden these various errors are taken into account in determining postcensal or intercensal population. An *estimate* is made of total migration gain or loss which is added to natural gain or loss to determine total population change. The combination of an accurate census and a well controlled community register, thus goes far toward solving the problem of determining postcensal and intercensal population.

TABLE III

Sweden: Population in Two Specified Groups of Communities in Blekinge, Kristianstad and Malmöhus Counties (as of Dec. 31 of Each Year)*

Year	Agricultural Communities			Towns

* Unpublished tabulations (D. S. Thomas).

Before bringing this paper to a close, one further point should be made, and that is in regard to the strong cyclical movement in migration series, and particularly in the series representing net internal migration for relatively homogeneous areas. The cycles of migration gain which urban areas show during periods of prosperity and of migration loss (or diminished gain) during depression, when cumulated, may be sufficiently strong to produce marked cyclical fluctuations in the total population. Since censuses may fall at any phase of these cycles, it is extremely important to be able to describe this movement and measure the annual deviations, if intercensal or postcensal population estimates are to be used as bases for birth and death rates. The accompanying charts and tables (Table III, Charts I and II) show the extent of cyclical variations in the agricultural population on the one hand, and the town population on the other, in the most southerly tier of Swedish counties. Straight lines drawn between the population at consecutive census years indicate the fortuitous timing of census enumerations. When such strong population displacements occur, computed rates may be considerably in error unless cyclical variation is taken into account. The negative displacement of the line of arithmetical increase between the censuses of 1900 and 1910 amounts to 2.8 per cent for the agricultural communities at the cyclical maximum of 1907, and the same year showed a positive displacement of 2.1 per cent for towns although this percentage was exceeded during the war years when the line of arithmetical increase was 2.8 per cent above the observed value for 1916, and almost as great in the 2 preceding years. These population cycles are, of course, caused by the cumulative and combined action of cyclical variations in births, deaths,

and migrations. Of these three variables, migration has played the dominant rôle in the particular series considered, and this situation is probably true, in general, of industrialized countries at the present time. Due to the strong age selectivity of migration, these series for total population by no means indicate the disturbance produced by cyclical variations upon specific age classes. I am at present assembling data on this point for a selected group of communities and, although the analysis has not been completed, there is evidence that the maximum cyclical displacement of the age groups 15-30 is several times as great as that of the total population. We are greatly in need of more complete and accurate information about selective migration and its temporal variations if we are to be in a position to allow for its influence upon population development in intercensal and postcensal population estimates. Until we have information of the sort derived from continuous registers, our estimates are likely to introduce serious errors in all vital indices.

In conclusion, it may be said that an efficiently controlled system of continuous population registers, combined with careful periodic enumerations of the resident population probably provides the best possible basis for reliable postcensal and intercensal population estimates. The operation of these systems in Sweden and The Netherlands has been described, and the sources and extent of the registration errors have been analyzed. Finally, the extent of cyclical variations in intercensal population, due largely to net internal migration, has been shown for selected Swedish regions and their implications for computing vital rates discussed. It is hoped that the experience of Sweden and The Netherlands may be taken as a guide for future American policy, for

our need of accurate population accounting is at least as great as theirs.

Epidemic Diarrhea of the New-Born*

III. Epidemiology of Outbreaks of Highly Fatal Diarrhea Among New-Born Babies in Hospital Nurseries

SAMUEL FRANT, M.D., F.A.P.H.A., AND
HAROLD ABRAMSON, M.D.

*Epidemiologist and Director, Bureau of Preventable Diseases; and
Field Epidemiologist, Department of Health, New York, N. Y.*

ONE of the main objectives of the medicine of today is the prevention and control of disease. The accomplishment of this aim is dependent, of course, on a sound understanding of the epidemiological characteristics of disease entities and on the application of the fundamental principles of modern preventive medicine to their control. To a gratifying degree success has attended efforts to erect suitable barriers against the occurrence and spread of certain diseases, as for example, typhoid fever, smallpox, diphtheria, and tuberculosis. However, present methods for the prevention of diarrheal disorders are still singularly inadequate. The persistent prevalence of enteritis not only among adults, but more particularly among infants and children, remains a problem challenging concerted attempts at solution. The situation is further complicated by the fact that almost as rapidly as public health measures are elaborated against recognized forms of diarrheal disorders, new types arise and confound efforts directed toward the ultimate goal.

In the summer of 1934 an unusual number of deaths were taking place among normally delivered new-born babies in the nurseries of one of the general hospitals in New York. The infants were succumbing to a fulminating form of intestinal intoxication whose clinical course could not be stemmed by recognized methods of therapy. When the outbreak finally abated 72 babies had been attacked and 32 had died.

Since this initial outbreak, somewhat over 3 years ago, we have had the unusual opportunity of following 23 such outbreaks in 15 hospitals giving maternity care. The statistical data are shown in Table I, as well as the sequence of events in connection with these outbreaks. From July, 1934, to July, 1937, we have followed the post-natal course of 4,594 live-born babies delivered at the times indicated in the table.

Among these, 711 cases of the disorder are known to have developed with an attendant average morbidity rate of 15.5 per cent. Of the sick infants 335 died, the average mortality rate being 7.3 per cent of the infants exposed, and the case fatality rate 47.0

per cent. In addition to the above morbidity and mortality, there also occurred an incidental neonatal mortality of 32 per 1,000 live-births from causes other than diarrhea, as well as a still-birth ratio of 29.

As the events of the various epidemics were followed we were impressed by the fact that we were confronted with a novel clinical entity in new-born babies, characterized by marked diarrhea, intense dehydration, toxicity, and early death. In a preliminary paper with Rice and Best,¹

the essential clinical features of this disorder, "Epidemic Diarrhea of the New-Born," were summarized and the fact was stressed that despite extensive bacteriologic, serologic, and pathologic studies, the etiology still remained obscure. The literature afforded meager information on the problem, but in view of the many communications received by us, we are of the opinion that the disorder is of more frequent and widespread occurrence than reports indicate.

Indeed, the prevalence of this epi-

TABLE II

FIGURE II—Infantile Diarrheal Death Rates, New York City, 1926–1936

demio form of diarrheal disease among new-borns is reflected in New York City's infant mortality statistics. For the past 10 years or more, considerable attention has been directed by public health authorities toward the new-born period of life and particularly toward the evident failure to effect a substantial reduction in neonatal mortality. Rice and his collaborators² have shown that the death rates from all causes of infants under 1 year of age have steadily decreased during the past 20 years, but that when the general death rates of infants under 1 month are considered separately, exceedingly little has been accomplished in lowering mortality in this age group.

The death rate in the age group, 1 to 12 months, inclusive, has decreased 68 per cent (from 63.8 in 1916 to 20.7 per cent in 1935); that of infants in the neonatal period only 21 per cent (from 36.8 to 29.1 per cent). In this connection analysis of the neonatal death rates from the point of view of diarrheal disorders strongly indicates

that the persistently high incidence of mortality among the newly-born is due in great measure to diarrheal disease. The curves in Figures I–IV illustrate this point clearly.

Figure I shows the constant downward trend 1926–1936 in infant mortality rates under 1 year of age. Figure II, representing diarrheal death rates during this same period of life, discloses a definite trend upward since 1932. But the curve for the age period 1 month to 1 year for diarrheal conditions displays a progressively descending trend (Figure III). Not so, however, with the curve in Figure IV, diarrheal death rates of babies under 1 month of age. Note the steady ascent in the trend in mortality for 1926–1936, and more especially since 1931–1932. These curves are a graphic indication of the importance of the previously unrecognized clinical entity "Epidemic Diarrhea of the New-Born," and its effect on New York City's infant death rate.

Epidemiologically this disease shows

FIGURE III—Infantile Diarrheal Death Rates, New York City, 1926–1936

the following characteristics: It involves specifically new-born babies during the first 3 or 4 weeks of life. No sex differences are present and, quite unlike the "summer diarrhea" of the past, but little variation is ex-

hibited in morbidity and mortality from one season to another. The data indicate that the rates are lowest during the fall and highest during the winter. There is, however, no clear-cut rise in the fall-winter season, thus linking the

FIGURE IV—Infantile Diarrheal Death Rates, New York City, 1926–1936

disorder to respiratory infections prevalent at this period, nor in the spring-summer months so frequently associated with other diarrheal conditions. The spring-summer incidence is but little different from that of the fall-winter incidence; the mobility, mortality and case fatality percentages are practically the same (Table II).

From the few reports which have appeared¹ and from personal communications with the authors, it seems that geographically the disorder has thus far been recognized only in cities of the United States and in other countries lying within the North Temperate Zone.* With respect to feeding, no differences are evident in the incidence of the disease among either breast-fed or artificially-fed infants. However, this distinction is no longer so sharply defined because of the present practice of giving supplementary feedings to nearly all new-born babies. Although infants born to mothers of the poorer classes of the city have been attacked most heavily, yet babies of the better classes are also affected, depending upon the operating interrelationships of the ward and private maternity services of the various individual hospitals.

Once the infection gains foothold in a nursery, the apparent mode of spread is from baby to baby lying in adjacent bassinets. Not infrequently a pre-existing nursery infection such as thrush or impetigo appears to set the stage for the outbreak. The first cases of the disorder occur sporadically. A short interval-free or latent period may then intervene, to be followed by a rapid succession of cases in close sequence. At times intervals of several days may elapse between new crops of

cases. The earliest instances of the disorder have occurred on the second day of postnatal life, other babies have been attacked as late as the 31st day, depending on the time of exposure to the disease.

During the investigations of the outbreaks, attention was directed toward tracing the path of transmission. Careful inspection was made of all possible common points of contact, such as may arise in the labor and delivery rooms, in the nursery and in the formula kitchen. In addition, a close check was made of the adult personnel on the obstetrical services, as well as of the nursery and diet kitchen staffs, and of the mothers in the maternity wards. However, despite extensive bacteriological studies of food, water, and equipment, and of nasal and pharyngeal secretions and stool specimens, the etiology of the disease and its point of origin were not revealed, nor could the inciting agent be isolated from the respiratory or gastrointestinal tracts of infected babies. Autopsy studies and tissue virus cultures likewise failed to reveal the etiological factor.

The prevalence of this epidemic form of diarrhea with its associated high mortality rates constitutes a situation requiring immediate attention. Moreover, in its broader aspects it is inextricably bound up with the general lowering of morbidity and mortality among the newly-born. As the initial epidemics were followed, we recognized early the necessity for a complete revision of present methods for the care of the new-born in hospital nurseries. We feel that the usual methods of obstetrical and pediatric practice and of preventive medicine have failed to cope efficiently with the situation. Epidemiologically, it would seem that very definite fundamental changes in the manner of conducting maternity and new-born services would prevent the

* These cities are Seattle, Wash.; Chicago, Ill.; Toronto, Can.; Memphis, Tenn.; New York, Rochester, and Buffalo, N. Y.; Teaneck, N. J.; Cincinnati and Cleveland, O.; Edinburgh, Scotland, and Garches, France.

occurrence not only of the disorder which we have described, but of infectious diseases in general among neonatal infants. Technics can be evolved which would break the chain of transmission of disease peculiar to the newborn.

Such measures we have discussed in a recent report.³ They comprise immediate closure of infected nurseries and suspension of maternity services. We have also advanced suggestions for the prevention of the disorder as well as of infectious diseases in general in the neonatal group. It is not within the scope of this paper to review in detail these methods. It will suffice to state that they are based on the principles of surgical asepsis, and aseptic nursing and medical care. They are founded on efficient and workable methods which have long been adopted in contagious disease hospitals and in child-caring institutions. In advancing these proposals we fully realize that in their details modification may be necessary to meet local conditions. However, the basic principles involved are fundamentally sound. The measures were formulated to fit the construction and equipment of maternity services as they exist today. As far as the future is concerned, complete revision must be made in plans for housing maternity and new-born services in hospitals, greater stress being laid on the individual care of the mother and her newborn baby.

In conclusion, it should be added that as a result of recognition of the problem, a comprehensive program has been mapped out in New York City in an effort to reduce neonatal morbidity and mortality. The Sanitary Code has been amended listing as a reportable condition "Diarrhea in the New-Born up to 3 weeks of age occurring in a hospital giving maternity care." The terminology is designated broadly to

include all types of diarrheal disturbances in order to determine early the existence of the epidemic form of the disease. We are also investigating all infant deaths under 1 year of age to determine by case history records and by post-mortem examinations the accuracy of diagnosis as listed on death certificates. This phase of the problem has been discussed in detail in the recent paper by Bundesen and his co-workers.⁴

SUMMARY

Attention is called to an unusual chain of outbreaks during the past 3 years of highly fatal diarrhea affecting new-born babies during their period of customary care in hospital nurseries. Extensive bacteriologic and pathologic studies have failed to shed light on the etiology of the disease. The epidemiologic features of the disorder are discussed and the fact is stressed that we are confronted with a situation requiring a closer scrutiny by public health authorities and by practising obstetricians and pediatricians of our present medical and nursing care of the newborn baby.

Although a satisfactory reduction has been evidenced in death rates from all causes among infants from 1 month to 1 year of age, an analysis of the vital statistics records of New York City indicates that we have accomplished exceedingly little in effecting a suitable lowering in the death rates among infants in the neonatal period. In fact, as far as diarrheal deaths are concerned, our data show a steady ascent in mortality among new-born babies during recent years. We attribute this increased mortality to the previously unrecognized clinical entity "Epidemic Diarrhea of the New-Born."

The Taxpayer and Public Health

... Taxpayers will not grudge the small part of their tax dollar which goes for public health if they are told in concrete terms what public health means to them.

Health administrators should travel incognito in buses and in other public places, tempting strangers to discuss the commonplaces of their administrative machinery. They will be surprised to find how few have any conception of the functions of the public health nurse or of a sanitary engineer. On the other hand, they will find to be remarkably prevalent superstitions about public health which ought long ago to have become extinct. They will find citizens complaining because the neighbor's house was not fumigated after a case

of poliomyelitis had occurred in it. They will find a small, hard-headed but important group who, when it has learned what the health officer does, will be more than ever dissatisfied; who quite sincerely believe that his efforts are more sentimental than beneficial: "All this rescuing of the unfit is dysgenic and eventually will ruin the race." And always there will be the uncompromising liberals who resent every encroachment on individual liberty. A reasoned defense of the intention of public health in its fundamental aspects must be presented from time to time.—J. Rosslyn Earp, *Health News*, New York State Health Department, Albany, N. Y., Dec. 20, 1937.

Experiments on Antirabic Vaccination With Tissue Culture Virus*

LESLIE T. WEBSTER, M.D.

Rockefeller Institute for Medical Research, New York, N. Y.

AN outstanding problem in rabies today is the control of canine infection. In humans in the United States Registered Area, the disease is not increasing, for the number of cases has remained at 50 to 100 per annum for 14 years and, even in the states in which the disease in dogs is most prevalent, has not risen above 2 to 5 annually. In small, wild animals the disease is sometimes present and in livestock may assume epidemic proportions. But rabies, as recognized in this country, is chiefly an infection of dogs and is transmitted mainly through their bite.

To control canine rabies, two measures generally have been invoked—first, elimination of strays and confinement or appropriate muzzling of owned dogs to check the spread of the virus; second, vaccination of the dog population to increase its resistance. Restrictions have always been unpopular in this country despite their success in England; vaccination here is becoming widespread although its beneficial effects are in dispute. According to Umeno and Doi, one injection of phenolized vaccine was given to 215,000 dogs in the province of Tokyo with the result that 0.07 per cent subsequently

developed rabies in contrast to 5.5 per cent among 30,000 unvaccinated dogs. Dennison reported similar favorable results in Alabama, but most observers find that the vaccine either does not protect the dogs (Schoening, Giese) or is virulent and induces rabies following vaccination (Giese, Michin, Schern, Hermann, etc.).

Krause, in his general review in the *Kolle, Kraus, Uhlenhuth Handbuch*, summarizes the problem well in stating that the question is extremely difficult to solve in the field and requires experimental evidence from the laboratory. This laboratory evidence, he thinks, is not yet at hand, inasmuch as the technic has involved the use of a test inoculation of virus which is either too small to yield comparable results in the unvaccinated controls or too massive to permit survival of the vaccinated group. Finally, workers on virus diseases in general raise two questions which bear on antirabic vaccination: (1) Is a non-virulent vaccine, especially when given in one dose, capable of immunizing dogs? (2) Is not the brain tissue vehicle which contains the virus responsible, in part, for post-vaccinal paralyses? The problem remains, therefore, to find an effective yet safe vaccine.

To develop such a vaccine, the following experiments have been carried out in our laboratory. First of all,

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

we chose as test animals mice of a selected Swiss strain, 100 times more susceptible to rabies than rabbits, guinea pigs, monkeys, and dogs in published tests. Next we discovered that the mice could be readily immunized against an intracerebral injection of test virus containing up to 10,000 lethal doses. A single intraperitoneal injection of at least 1,000 intracerebral lethal doses rendered mice resistant within 14 days and over a period of at least 9 months. Neutralizing antibodies were likewise present.

Having learned that these mice could be measurably immunized, we then examined various commercial preparations with respect to their immunizing capacities. None immunized the mice when given according to directions in a single dose in a quantity at least 10 times that administered to dogs per gram of body weight. If 6 or more doses were employed, however, a few vaccines immunized against 10 to 100 lethal doses, especially those found to contain virulent virus. One or two phenolized preparations containing no virulent virus showed mild immunizing potency following repeated injections. In all, we concluded that a single dose of present commercial canine vaccines does not render mice immune to the smallest measurable dose of test virus.

At this point, the possibility of a new source of vaccine was investigated. Preparations in current use are composed largely of virus-containing brain or cord tissue of rabbits, sheep, or monkeys. Nervous tissue is not only a superfluous but a potentially dangerous vehicle which may produce paralysis following vaccination, hypersensitivity, or secondary infections. Until now, however, no other source of virus has been available and the nervous tissue has remained inseparable from the virus. In the fall of 1936, however, the propagation of rabies virus

in culture media outside the animal body was reported by Kanazawa in Japan, and by Webster and Clow in New York. Our cultures have been continued unremittingly now for 95 passages and have become uniformly virulent through the 1/10,000 dilution. The technic of propagation is carried out in the following manner. Using aseptic technic throughout, 50 c.c. Erlenmeyer flasks are prepared with 4 c.c. of Tyrode solution containing 10 per cent normal monkey serum plus 0.02 c.c. of a suspension of minced mouse embryo brain. This flask culture medium is then inoculated with 1 c.c. of a 1 to 100 dilution of the brain of a mouse prostrate on the 7th or 8th day following an intracerebral injection of rabies virus. At 3 to 4 day intervals, the contents of the flask is withdrawn to a centrifuge tube, allowed to settle, and 2.5 c.c. of the relatively clear supernatant is transferred to a second culture flask. This passage technic is repeated routinely and the virulence of the culture virus is titrated by inoculating the material intracerebrally in tenfold dilutions in Swiss mice. As a source of vaccine the culture virus has the following advantages. It contains very little brain tissue, is practically water-clear, is of measurable, uniform virulence, keeps at least 60 days in bulk or in a frozen and dried state at icebox temperature.

This culture virus was tested for its ability to immunize mice. One-quarter c.c. of the undiluted culture, equal to 80,000 intracerebral lethal doses, was harmless when injected intraperitoneally and protected them in 14 days against a test intracerebral injection of 1,000 lethal doses of mouse brain virus. One-tenth of this amount of culture vaccine was likewise effective but 1/100, containing only 800 lethal doses, was insufficient for immunization. Immunity, when produced, endured at least 9

months and was accompanied by protective antibodies.

Attempts were then made with culture virus to immunize beagle puppies. At the outset it was necessary to establish the lethal dose for dogs of the virus to be used in testing the success of the vaccination. Mouse-brain virus, obtained originally from a skunk, was injected intracerebrally into the dogs in 1 c.c. amounts in dilutions ranging from 10^{-2} and 10^{-8} gm. In 5 tests in which the 10^{-4} dilution was given, all of 5 dogs succumbed; in 6 tests in which the 10^{-5} dilution was given, 9 of 11 dogs succumbed; in 6 tests in which the 10^{-6} dilution was given, 2 of 8 dogs succumbed. The minimum lethal dose of the virus for dogs in this intracerebral test was taken as the least amount giving 50 per cent or more mortality, namely, 1 c.c. of 10^{-5} dilution. Dogs were vaccinated with relatively small amounts of culture virus, 5,000 to 20,000 mouse lethal doses, barely 20 times that required to immunize mice. The vaccine has proved harmless to all 45 dogs thus far treated and has immunized them as follows. In the first test, 7 of 7 vaccinated dogs resisted 1

lethal dose of test skunk virus given 3 weeks later. In the second test, 4 of 4 vaccinated dogs resisted 1 lethal dose and 1 of 3, 10 lethal doses. In the third test, 3 of 3 vaccinated dogs resisted 1 lethal dose and 2 of 3, 10 lethal doses. In all, 14 vaccinated dogs all resisted 1 lethal dose fatal to 9 of the 11 controls. This difference is statistically significant. Likewise, 3 of 6 vaccinated dogs resisted 10 lethal doses fatal to all 5 tested controls. This difference, however, is not significant. The 15,000 mouse lethal doses of culture vaccine which immunized dogs against 1 test lethal brain dose can be contained in 1 c.c. and can be increased apparently without harm to 1,000,000 mouse lethal doses. With a larger amount of mouse lethal doses in the vaccine, a greater resistance is expected.

This evidence that dogs can be successfully immunized with a single injection of culture virus concludes our present report. Further experiments aimed at reducing still further the virulence of the culture vaccine without destroying its immunizing potency are now in progress and will be submitted in the near future.

Relation of Lymphocytic Choriomeningitis to Acute Aseptic Meningitis (Wallgren)*

R. D. BAIRD, M.D., AND THOMAS M. RIVERS, M.D., Sc.D.

*Hospital of The Rockefeller Institute for Medical Research,
New York, N. Y.*

THE discovery of the virus of lymphocytic choriomeningitis was reported in 1934 by Armstrong and Lillie.¹ In 1935, Traub² described experiments showing that the virus is frequently demonstrable in normal-appearing mice. Also in 1935 Rivers and Scott³ recovered the virus from the spinal fluid of 2 patients suffering with a disease fulfilling the criteria laid down by Wallgren⁴ for the diagnosis of "acute aseptic meningitis" and definitely showed that the virus was the etiological agent responsible for their malady.

Wallgren⁴ considered acute aseptic meningitis a clinical entity and laid down the following criteria for its diagnosis: Sudden onset of meningeal symptoms associated with a slight or moderate increase in the number of cells, especially lymphocytes, in a bacteria-free spinal fluid; a benign course with no complications; the absence of a focus of acute or chronic infection in the vicinity of the brain, for example sinusitis; and the absence from the community of diseases known to be

capable of producing irritation of the meninges.

Inasmuch as the 2 proved cases described by Rivers and Scott^{3, 5, 6} and the one proved case cited by Armstrong and Dickens⁷ satisfied criteria for the diagnosis of acute aseptic meningitis it has been suggested by certain workers that all cases satisfying these criteria are caused by the virus of lymphocytic choriomeningitis. However, Rivers and Scott⁶ have already presented some evidence that all cases of acute aseptic meningitis are not caused by this virus, and recently Armstrong and Wooley⁸ obtained additional evidence which leads them "to feel that the clinical entity 'aseptic meningitis' is made up of more than one etiological entity." In spite of these reports there is still a tendency on the part of some investigators and clinicians⁹ to assume or to imply that all cases of acute aseptic meningitis are caused by the virus of lymphocytic choriomeningitis. In view of this, we have examined the spinal fluid and blood from a number of cases of aseptic meningitis in order to determine how frequently this new virus is responsible for disease of the central nervous system in man. Furthermore, we have examined the his-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

tories of these cases and the ones reported in the literature to see if it is possible to differentiate clinically the ones caused by the virus from those that are not.

For therapeutic purposes, Lepine and his coworkers¹⁰ have infected human beings with a murine strain of lymphocytic choriomeningitis virus; about half of the inoculated patients developed meningeal involvement while the others exhibited fever and influenza-like symptoms. Furthermore, it has been shown⁸ that many individuals without histories of having had any involvement of the central nervous system possess neutralizing antibodies against the virus of lymphocytic choriomeningitis. Consequently, it appears that an individual can be and not infrequently is infected with this virus without the central nervous system being obviously involved. Since we have been chiefly interested in the relation of the virus to acute aseptic meningitis we have not directly concerned ourselves with the non-meningeal form of disease caused by it.

MATERIALS AND METHODS

Spinal Fluid and Blood—Specimens of spinal fluid and blood from 65 cases of suspected acute aseptic meningitis were sent to us by physicians in different parts of the United States and Canada. We were unable to see the cases or to direct the manner in which they were handled; consequently, the histories and physical examinations were not so complete as they might have been, and many specimens essential for a laboratory diagnosis of lymphocytic choriomeningitis were not obtained. A number of the specimens came quite a distance by mail and this may account for our inability to recover the virus from certain cases.

Later we discovered that 31 of the 65 cases did not fulfil the requirements

for a diagnosis of acute aseptic meningitis; among the 31 cases, diseases such as tuberculous meningitis and post-infection encephalitis were represented. The results obtained with material from this group served as excellent negative controls, but otherwise were of no significance.

Animals—Mice and guinea pigs from stocks known to be free from the virus of lymphocytic choriomeningitis were used in all experiments and tests.

Isolation of Virus—Details of the technic of isolating the virus of lymphocytic choriomeningitis from materials obtained from human beings and the method of identifying it have been described by Rivers and Scott.^{5, 6}

Neutralization Tests—The neutralization test employed in this work is different from the one used by Scott and Rivers⁵ and Wooley, Armstrong, and Onstott¹¹; it was devised by Muench and Scott and a detailed description of it with the statistical data supporting it will appear later. All neutralization tests in this laboratory have been done with the W.E. strain of virus. From an examination of the results obtained with known positive sera and with known negative sera it became obvious to Muench and Scott that a 10^{-2} dilution of the virus was the critical one in the tests regardless of variations in the titer of the virus emulsion used. Such a statement applies only to this particular strain of virus which has been passed in guinea pig brains since isolation. In order to use another strain of virus in the manner to be described, its critical dilution would have to be determined by statistical methods.

The brain of a guinea pig inoculated with the W.E. strain of virus is removed aseptically at the height of the disease; by weight a 10 per cent emulsion in Locke's solution is made and called virus stock emulsion. A 10^{-2} dilution

is made of the stock emulsion and 1 c.c. of it is mixed with 1 c.c. of each serum to be tested. In all experiments a positive and a negative control are included. The mixtures of virus and serum are allowed to stand in an incubator at 37° C. for 1 hour, after which 0.5 c.c. of each mixture is injected subcutaneously into each of 4 guinea pigs; the animals are observed for 18 days. If 3 or 4 pigs survive, neutralizing antibodies are present; if 3 or 4 pigs die, neutralizing antibodies are considered to be absent; if 2 pigs die, the significance of the result is doubtful.

Results of tests made in the manner just described are much easier to interpret than are those of tests previously used. It is possible that a weakly positive serum may be missed occasionally. However, such an error is not to be deplored in this type of work.

RESULTS OF ATTEMPTS TO DEMONSTRATE VIRUS IN SPINAL FLUID AND BLOOD

Spinal fluid from 41 patients and blood from 11 of them, collected during the acute stage of disease, were examined for the presence of virus. Twenty-three of the specimens of spinal fluid and 9 of blood came from 23 cases that subsequently were found not to satisfy the criteria for a diagnosis of acute aseptic meningitis. Spinal fluids from only 2 of the patients whose convalescent blood showed neutralizing antibodies were examined, and they were collected late in the course of the disease. In none of the specimens of blood or spinal fluid was virus demonstrated.

Spinal fluid from 1 case of aseptic meningitis produced a mild febrile illness in guinea pigs, but this illness could not be produced in more than one or two successive lots of pigs. Furthermore, the pigs after recovery were not immune to the virus of lymphocytic choriomeningitis. If an in-

fectious agent was responsible for this mild illness in the animals its source and identity were not determined.

RESULTS OF NEUTRALIZATION TESTS

Attempts were made to obtain serum from patients early in the course of disease and again 6 or 8 weeks after the onset of illness. In some instances we obtained both specimens; in others we secured a specimen only at the onset or after recovery. With these sera neutralization tests were promptly carried out in the manner described above.

Neutralization tests were performed on sera from 32* cases satisfying the criteria for a diagnosis of acute aseptic meningitis. On a basis of the time of collection of the sera and the results of the neutralization tests the cases have been grouped in the following manner:

One proved case of lymphocytic choriomeningitis; serum did not neutralize at onset but did after recovery.

Seven presumptive cases of lymphocytic choriomeningitis; serum was not collected at onset of illness, but the specimen secured during convalescence contained neutralizing antibodies. Under such conditions it was impossible to be certain that the antibodies were not the result of a previous unrecognized infection with the virus.

Twenty-one cases of acute aseptic meningitis not caused by the virus of lymphocytic choriomeningitis; demonstrable neutralizing antibodies were not present in the sera collected from patients who had recovered.

Three equivocal cases; antibodies were not present in sera collected at onset of disease, but it has been impossible to obtain sera from the patients after they had recovered.

For the sake of convenience both proved and presumptive cases of lymphocytic choriomeningitis will be referred to as positive cases in the remainder of the paper, while cases of acute aseptic meningitis not caused by the virus of lymphocytic choriomeningitis

* We had 34 cases satisfying the criteria for a diagnosis of acute aseptic meningitis, but from 2 of them we received only spinal fluid for examination.

TABLE I

Summary of Signs and Symptoms Found in 23 Positive and 19* Negative Cases

Signs and Symptoms	23 Positive			19 Negative		
	Present	Absent	No Record	Present	Absent	No Record
Influenza-like prodrome	16	7	..	3	15	1
Fever	20	2	1	17	2	..
Headache	20	2	1	15	2	2

Babinski's reflex	7	9	7	5	12	2
Localized neuropathy	5	18	..	5	14	..
Residual neuropathy	3	20	..	1	18	..

* Detailed records not available for 2 of the 21 negative cases.

gitis will be spoken of as negative. Thus, from the results of the neutralization tests, 29 of 34 cases of aseptic meningitis can be classified as positive or negative in regard to having been caused by the virus of lymphocytic choriomeningitis. Of the 29 cases, 8,

or 28 per cent, were either caused or presumably caused by the virus in question, while, 21, or 72 per cent, were not. Of course one should keep in mind the possibility that an occasional patient infected with the virus may not develop antibodies.

It is of interest to note that W.E., a proved case of lymphocytic choriomeningitis, still possessed neutralizing antibodies against the causative agent 2 years after recovery. On the other hand, W.S., a presumptive case 8 years of age, had, as shown by 2 tests, neutralizing antibodies 6 to 8 weeks after the onset of illness, but no demonstrable protective substances 8 months later.

* Records of the cell counts for 2 of the 21 negative cases were not available.

ATTEMPTS TO DIFFERENTIATE CLINICALLY THE CASES OF ACUTE ASEPTIC MENINGITIS CAUSED BY THE VIRUS OF LYMPHOCYTIC CHORIOMENINGITIS FROM THOSE NOT SO INDUCED

In the literature 15 positive or presumptive cases of lymphocytic choriomeningitis^{5, 7, 11, 12, 13,* 14, 15, 16, 17} have been described; these include 3 positive cases reported in a preliminary note by

* The tests on the cases reported by Dr. Dominick were done in our laboratory and the results are included in our tables.

Rivers and Scott¹⁶ which Scott will report in detail later. In addition to these 15 cases we have found 8 others during our recent experimental investigations. Thus, there are 23 cases of acute aseptic meningitis caused by the virus of lymphocytic choriomeningitis that are available for comparison with our 21 cases not induced by the virus in question. Therefore, it seemed of interest to determine whether there is a significant clinical difference between the two groups. The important clinical findings in the two groups are summarized in Tables I-III and in Chart I.

A comparison of the findings in the two groups reveals that a large number of the positive cases gave a history of an influenza-like prodrome, *i.e.*, general malaise, generalized pains, headache,

upper respiratory infection, and fever, 1 to 3 weeks before the onset of meningitis, while from only a few of the negative cases was such a history obtained.

With the onset of meningitis the signs and symptoms in the positive and negative cases were similar and occurred with equal frequency in the two groups. Headache, nausea, vomiting, nuchal rigidity, abnormal deep reflexes, and fever were the usual findings.

A localized neuropathy was observed with approximately equal frequency in the two groups. Four negative cases (L.E., B.'s patient, J.R., and Ben S.) showed a transient facial paralysis, while another one (C.G.) developed a chronic arachnoiditis of the posterior fossa. One positive case (Adam M.) had a transient facial paralysis: an-

* Detailed records not available for 2 of the 21 negative cases.

other (R.E.S.) showed transient unilateral sensory changes in the lumbar region; 3 others (A.W., B.C., and F.A.) developed bladder symptoms and muscular weakness and loss of sensation in the lower extremities. One (B.C.) of the last 3 patients mentioned also developed a facial paralysis which was still complete with electrical reaction of degeneration 7 weeks after the onset. The condition of A.W. was improved several months after the onset of the illness; the present condition of the patient has not been recorded. F.A.'s condition did not improve and when she was operated upon 6 months after the onset of her illness a chronic arachnoiditis involving the cord was found.

There were no significant differences in the amounts of protein, sugar, and chloride found in the spinal fluids of the two groups; nor were the hemato-

logical findings of aid in differentiating positive from negative cases. However, a comparison of the cell counts of the spinal fluids in the two groups shows that the positive cases tended to have more cells than did the negative. For example, 48 per cent of the positive cases at some time during the acute stage had more than 1,200 cells per c.mm., while this was true of none of the negative cases (Chart I).

There was no significant difference in the age of patients in the positive or negative groups. Furthermore, 10 of the 23 positive cases were in patients under 20 years of age, the 2 youngest being 5½ years and 8 months old respectively, a finding somewhat different from that reported by Armstrong and Wooley⁸ and Wooley, Armstrong, and Onstott,¹¹ who, in view of their investigations, are inclined to believe that obvious infection with the virus of

lymphocytic choriomeningitis is relatively infrequent in infants and children.

COMMENTS AND SUMMARY

From the evidence presented in this paper it is obvious that all cases of acute aseptic meningitis (Wallgren) are not caused by the virus of lymphocytic choriomeningitis. The etiological agent or agents responsible for the cases not so induced are not known. Furthermore, from the records^{12, 17} of 3 patients with lymphocytic choriomeningitis it appears that certain cases of the disease, because of the extent of paralysis and sequelae, do not satisfy the criteria laid down by Wallgren for the diagnosis of acute aseptic meningitis.

It is difficult or impossible to differentiate by clinical means alone the cases of acute aseptic meningitis caused by the virus of lymphocytic choriomeningitis from those not produced by the agent; however, the spinal fluid cell counts in the cases studied tend to be higher in the former group than in the latter.

Children and even infants are not infrequently attacked by the virus of lymphocytic choriomeningitis.

Difficulties Encountered in Pneumococcal Type Determination*

ANNABEL W. WALTER

Bureau of Laboratories, Department of Health, New York, N. Y.

WITH the increasing availability of therapeutic serum for use in the treatment of pneumococcus pneumonia, rapid and reliable determination of the type of infecting organism is being demanded by more and more physicians. Sera for treating some of the types of pneumococci that occur less frequently will probably be produced in the near future, with the result that more laboratories will find it necessary to test not only for Types I, II, and III, but also for all other types for which therapeutic serum may be available. A number of methods of type determination have been presented.¹⁻¹⁸ Certain difficulties have arisen with each, and it is of some of these as we have experienced them that we propose to speak. No claim of originality is made for our methods; most of them were developed under the direction of the late Georgia Cooper whose devotion and application to the laboratory phases of the pneumonia problem resulted in many advances in type differentiation and serum production. My appreciation is also due Kathryn Blount and the other members of the present staff whose coöperation and interest have made it possible to accomplish a steadily increasing amount of work.

We have tried to group the difficul-

ties according to their sources: in the specimen, the sera used for testing, the methods, and the equipment.

Specimen—Sputa, swabs from the throat, gastric contents,¹⁹ cultures, pus, spinal fluids, pleural fluids may all be used for type determination.

Sputum should be fresh. The ideal age for the Neufeld reaction is less than an hour. If such rapid transportation from the patient to the laboratory is not feasible, the specimen should be kept in the icebox until it can be sent in, to delay as much as possible the overgrowth of organisms other than pneumococci. Some physicians have the impression that a fairly large amount of sputum is necessary, and will continue to collect the patient's expectorations over 12 to 24 hours. As small a volume as $\frac{1}{4}$ c.c. is usually enough for the Neufeld reaction, for a culture on a blood agar plate and, if necessary, for inoculation in a mouse.

The sputum should be collected in a clean, dry and preferably sterile container with no disinfectant. We prefer a clear glass wide-mouth bottle about $1\frac{3}{4}$ " wide and $2\frac{1}{2}$ " high with a screw cap. The wide mouth is more convenient for the patient. Clear glass makes it easier to determine the consistency and color of the specimen and facilitates the removal of such more promising portions as bloody or mucoid flecks to a Petri dish for examination.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

The bottle supplied in New York City for sputa to be examined for tubercle bacilli contains a liquid disinfectant which will dilute a thin watery specimen so much that the task of finding organisms when the Neufeld reaction is employed is almost impossible. Some disinfectants also have an inhibitory effect on the capsular swelling and, unless the specimen is very thick, will kill all the organisms so that attempts to cultivate them either by mouse inoculation or on artificial media are futile. The removal of sputum from the container to a Petri dish is easy if a 2 c.c. rubber bulb on a glass tube about 3" by 5/16" with a blunt point is used. In collecting sputum, care should be taken to make sure that the sample is actually pulmonary exudate raised by coughing, not retro-pharyngeal mucus or saliva.

In cases where sputum is not produced, as in infants and small children, suitable material for typing may be obtained by gently touching the pharynx with a sterile cotton swab on a long applicator to induce a cough and collecting on the swab any mucus produced.¹⁰ The swab is then sent in a dry, sterile tube to the laboratory where it is twirled thoroughly in 1/2 c.c. of serum broth in order to remove the sputum, and then rolled against a dry part of the tube to squeeze out as much of the suspension as possible. If the pneumococci are too few for typing by the Neufeld reaction, they may be concentrated by centrifugation at a fairly high speed for 20 to 30 minutes and then resuspended in one or two drops of the supernatant fluid. We have obtained very good results with such material both by the Neufeld method and by mouse inoculation.

When blood cultures are made, it is essential the blood be added to suitable broth and mixed thoroughly to prevent clot formation as soon as it is

drawn, and that the culture be either incubated immediately or stored at a temperature between 8 and 15° C. until it can be incubated. Broth cultures should be observed at intervals for growth, which may occur in from 12 hours to 3 days. When growth occurs, the type may be determined by the Neufeld reaction. Care should be taken that too much blood is not used; up to 2 c.c. for 50 c.c. of broth, or 1 c.c. for 25 c.c. of broth, is adequate. Much more prognostic value is attached to blood cultures made in poured agar plates from which the degree of bacteremia may be estimated and followed.

For growing pneumococci, it is essential that the medium used will support growth but will not cause rapid autolysis. We have found beef-heart broth and agar containing 0.2 per cent disodium phosphate as a buffer and with no sugar added very satisfactory. Directions for their preparation as carried out in this laboratory are given here in full because of the many requests we have had for details.

Soak chopped beef heart from which fat has been removed in tap water in the proportion 1 lb. to 1 liter overnight in the refrigerator. Boil until meat clumps and turns brown. Strain through cheese cloth. Test for carbohydrates. Good broth contains 1.2-1.5 mg. of total carbohydrate per c.c. Add 1.0 per cent Parke-Davis peptone and 0.2 per cent disodium phosphate. Dissolve by boiling with broth. Adjust reaction to pH 8.1 with sodium hydroxide. While the reaction is being adjusted, keep broth at boiling point to bring down precipitate. Final reaction should be pH 7.4-7.7. Filter through paper while hot. (Cotton is sometimes placed below paper to keep it from breaking.) Tube or bottle and sterilize in autoclave at 15 lb. pressure for 1/2 hour.

Test for support of growth by inoculating several tubes with 0.2 c.c. of the supernatant growth of blood broth cultures of several types of pneumococci (we use Types I, II, III, V, IX). Compare density of growth at 18 hours with known turbidity standards such as meningococcus standards. Determine pH of 18 hour growth. Broths whose pH fall below 6.8 as a result of digestion by the

organisms of the sugar in the media are unsatisfactory because pneumococci are injured by an excess of acid.

For media for maintenance of stock cultures, 3 per cent horse blood (citrate)* is added to the broth a few days before it is to be used.

The same stock may be used for agar medium.

Spinal fluids from pneumococcic meningitis should be examined as soon as possible. The organisms can be typed by the Neufeld reaction. If they are few, they may be concentrated by centrifugation or cultured in blood broth. Since only one type of pneumococcus is usually found in spinal fluids, a search for a possible mixed infection is not indicated.

Pus from ear infections or from peritonitis often contains many intracellular organisms. Dilution with broth may facilitate typing by the Neufeld reaction or cultures in blood broth may be made and typed when growth occurs.

Fluid aspirated by means of a syringe from the lung is usually too small in quantity for direct examination and requires cultivation in broth.²¹

Serum—For microscopic and macroscopic agglutination and precipitation tests, antisera produced in horses are employed. Each serum should be tested before use to determine its titer with the homologous strain and the degree of cross-reaction with all other types of pneumococci. Those sera which give a strong reaction with the homologous strain in a dilution which excludes cross-reactions (preferably 1-5 to 1-20) are most suitable. The dilution recommended should be indicated on the label of each vial. Sera produced in horses are not satisfactory for the Neufeld reaction.

For the capsular swelling reaction, antisera produced in rabbits are used. We have set an arbitrary agglutinin

titer of 1-200 for our rabbit sera but the swelling titer may also be used as a criterion for adequate strength. Such sera should have a swelling titer of at least 1 to 15 to permit them to be combined in groups of at least 5 types and still have sufficient excess antibody present that reactions may be obtained with sputa containing many pneumococci or large amounts of soluble specific substance from autolysis. Each serum should be tested for cross-reactions with all other types of pneumococci. Sera which react nonspecifically should not be issued. We have found it more satisfactory to add methylene blue as the preparations are set up than to add to it to the rabbit serum in bulk.

Aging in the cold does not cause appreciable deterioration of either horse or rabbit serum. Although the specific titer drops slightly within the first year, nonspecific reactions become less the longer the serum is kept.

Method—In our hands, the Neufeld reaction has proved to be the most rapid and reliable method of pneumococcal type determination. The technic we use has been published previously but I quote it here.

Part of the sputum is placed in a Petri dish. The remainder is stored in the icebox until all tests are completed. "With a tiny loop or a straight wire place a very small amount of material on a cover glass, mix with 4 to 40 times the amount of serum as required and a standard loopful (0.01 c.c.) of Loeffler's methylene blue. Seal on a hollow-ground slide with cedar oil, place a drop of oil on the cover glass and examine with the oil immersion lens. Inverting the slides with the ends on side rests, and cover glasses down for a short time before examination seems to facilitate the examination, especially when the specimen is thin. The heavier elements, including the pneumococci, settle on the cover glass and may be more easily examined. A fairly good microscope is necessary and a powerful microscope light is a great aid. When only ordinary light is available the drops may be placed on flat slides and covered with cover glasses. When

* 1 per cent citrate (10 per cent citrate added—1 part in 10).

CHART I—Pneumococci with normal capsules.
No reaction

CHART II—Pneumococci with capsules
swollen. Positive reaction

the organisms are few they were somewhat more difficult to find in thin preparations."¹⁷

The procedure is to observe the reaction with 6 combinations of 4 to 6 antisera among Types I to XXXII²² are divided. When we started using combinations 5 years ago, we made groups of as many as 12 sera,¹⁷ but have since found that some sera may be too weak for consistent results in so great a dilution. If no reaction is observed immediately, we examine the preparations again after an hour or so.

The criticism we hear most often of the Neufeld method is "there are plenty of organisms but they do not react." Usually the failure to obtain a reaction may be traced to the relative amounts of sputum and serum used. Consistent results cannot be obtained by using equal parts of sputum and serum. It is unfortunately misleading that positive reactions do sometimes occur with such proportions. In order to be sure to have an excess of serum present, we use two separate loops of 28 gauge platinum wire—a very small one, 1 mm. in diameter, for placing the fleck of sputum on the cover-glass, and a larger one, 4 mm. in diameter, for the serum and the methylene blue. A straight wire may be used for

mucoid specimens loaded with organisms. From 4 to 10 times as much monovalent serum as sputum, and from 10 to 40 times as much combined serum as sputum seem to be satisfactory proportions for specimens containing moderate to large numbers of pneumococci. It is advisable to examine the first preparation made immediately to see if there are enough organisms present. With specimens containing very few, larger amounts of sputum will necessarily be required. The identity of organisms which resemble pneumococci in the hanging drop, but fail to react with any of the sera available, can only be determined by cultural examination.

It sometimes happens that a small amount of sputum collected in a paper container or one that is not air-tight will reach the laboratory nearly dried up. Broth may be added to resuspend such material. Another extreme is met more often: the specimen is extremely tenacious and very thick. When preparations made by mixing with serum are examined microscopically, large masses of material are seen in which organisms that do not react are noted. There is reason to believe the serum has not reached the organisms because of the nature of the sputum.

With such material, it is well worth while to try the technic proposed by Kohl²³: a small amount of sputum is thoroughly mixed with about 5 c.c. of saline (0.85 per cent) or broth in a Petri dish. The flecks that float to the top are used for the Neufeld reaction. These preparations are very easy to examine because of the extreme clarity of the field.

When the specimen is thin some strains, especially Type III, show a marked tendency to be agglutinated by the specific serum. Large clumps of organisms are formed with the swollen capsules distinguishable only around the edge of the masses. As few organisms remain isolated in such preparations a thorough examination must be made lest they be overlooked entirely.

A small proportion of sputa will be found to contain two or more types of pneumococci. For this reason, it is not enough to find a positive reaction. One must be sure there is no reaction with any of the other diagnostic sera being used. If more than one type is found, some indication as to which is the causative agent may be obtained from the relative proportion of the different organisms present and from a knowledge of the incidence of the different types of pneumococci in healthy individuals. For example, types III, VIa & b, and XXIII are relatively more common in normal throats than are other types. Examination of a second specimen from the same case may reveal the presence of only one type.

If hanging drop preparations are made, the slides and cover-glasses must be thin. Slides less than 1.5 mm. in thickness and No. 1 cover-glasses allow enough working distance for focusing to the bottom of the drop. Cedar oil is supplied in different grades of viscosity. A medium weight is the best for year-round use.

There are disadvantages as well as

advantages in the use of flat slide preparations for the Neufeld reaction. Among the advantages, is ease in setting up the preparations. Plain slides are uniformly thinner than hollow-ground ones, so adequate working distance is assured. A less powerful microscope lamp is required. Focusing is easier too, with only one plane to be examined. There are three chief disadvantages: first, it is a difficult and time consuming task to seal flat slide preparations so they may be reexamined after an hour or so. As the drops dry around the edge, the organisms take on an appearance that may be mistaken for a swelling. The second disadvantage is that large drops of mixed sputum and serum are apt to seep out around the edges of the cover-glass and contaminate both the fingers of the operator and the lens. The third and most serious objection is that sputa that are very tenacious or that contain solid particles prevent the cover-glass from lying flat on the slide. When an attempt is made to focus on such a preparation, the cover-glass may move up and down with the lens in a very disturbing manner.

Specimens which fail to type by the Neufeld reaction may be examined further by the intraperitoneal inoculation of $\frac{1}{4}$ c.c. into a mouse which is observed at frequent intervals for signs of sickness. Symptoms may occur in 4 or 5 hours. At that time or in 18 or 24 hours, a puncture of the peritoneum is made. For this purpose, we use a capillary tube about 75 mm. long and 1 mm. in diameter drawn to a sharp point. The point is inserted into the peritoneum and a small amount of fluid is drawn out. The fluid will flow more readily if the mouse is held with the abdomen down. A small rubber bulb may be used to exert suction if necessary. The material obtained is examined by the Neufeld reaction, care

being taken that only minute amounts of exudate are used. Mice which show no organisms on puncture and continue in good health are killed at the end of 5 days. If the mouse dies or is sick enough to be killed, the peritoneum is opened and the exudate placed on the cover-glasses with a straight wire. Cultures are made in blood broth and on blood agar plates from the exudate and also from the heart's blood.

We have found the Neufeld reaction much more satisfactory than the stained slide agglutination technic or macroscopic agglutination and precipitation methods for examining peritoneal exudate, chiefly because of the absence in rabbit sera of the cross-reactions that occur to some degree in nearly all horse sera.

The extreme susceptibility of the mouse to pneumococci may lead to errors in typing. It succumbs so readily to most strains that if more than one type of organism is present, death from the more virulent type will usually occur so promptly that the presence of the other type will not be detected.

For example: a few Type III organisms from the throat of a patient whose sputum contains a moderate number of pneumococci of some other type will almost always cause death from Type III septicemia of a mouse inoculated with such material. If the mouse test only is used for typing, the other organism will be overlooked. An attempt to hold back a virulent type in a mouse if the presence of a less virulent type is suspected may be made by injecting an appropriate amount of serum for the virulent type along with the sputum.²⁴

As a routine procedure, we culture each specimen received on a fresh blood agar plate in such a manner as to produce separate colonies.

A moderate amount of material on a platinum loop is streaked back and forth 10 or 15 times without lifting the loop from the surface. The loop is sterilized by heat and an equal number of streaks are made at right angles. This technic will almost al-

ways result in isolated colonies over the entire surface of the plate. The presence of hemolytic colonies may be detected more easily if a cut is made with a straight wire part way through the agar from the beginning of the streak diagonally across the plate.

The plate is incubated for 18 to 24 hours and the approximate percentages of the different types of colonies are recorded. Fishings to blood broth are made of green-producing colonies, at least one of each type observed, and are checked by the Neufeld reaction. If they do not react, bile-solubility tests are carried out to determine whether they are pneumococcus or streptococcus viridans. The technic we use is as follows:

Transplants are made from fresh blood-broth cultures to plain broth using 0.2 c.c. of the supernatant growth as an inoculum. After incubation for 18 to 24 hours, 0.2 c.c. of each culture is combined with 0.1 c.c. of ox-bile in a small tube ($3 \times \frac{3}{8}$ "). Similar amounts of culture are combined also with 0.1 c.c. of broth as controls. Cultures which produce a granular or flocculent sediment are mixed well before use. As a guide to the clarity and color to be expected, one tube containing 0.2 c.c. broth and 0.1 c.c. bile is included. The tubes are incubated in a water bath at 45° C. for 1 hour and then examined. Those cultures which lyse completely in bile are considered soluble, and therefore pneumococci. The bile used must necessarily be crystal-clear. Centrifugation may be enough to clarify it but sometimes filtration is necessary. Each new lot of bile should be tested with known pneumococcus and streptococcus viridans cultures.

We also make a fairly thick smear of each sputum which we stain by Gram's method. This is not of much value in deciding whether or not pneumococci are in the specimen but the presence of numerous Gram-negative bacilli or Gram-positive cocci in bunches may be of interest to the physician.

From about 20 per cent of the 367 sputa we examined last winter (November 1, 1936—April 30, 1937), no indication as to the organism causing

the disease could be obtained by the methods described above.

Equipment—Adequate lighting for microscopic examination for the Neufeld reaction is most important. A fairly good microscope is necessary and an inclined binocular is certainly easier on the examiner. Sufficient light is absolutely essential. We use high power lamps equipped with 500 watt bulbs. There are, however, other lamps equipped with 100 or 200 watt bulbs on the market which should be satisfactory and less expensive to operate.

Hollow ground slides and cover-glasses of proper thickness and two platinum loops of different sizes will speed up the examinations.

SUMMARY

Specimens for pneumococcal type determination should be fresh and should contain no disinfectant.

Labels on vials of diagnostic horse serum should indicate the dilutions best suited for macroscopic and microscopic agglutination as determined by tests with all types of pneumococci. Rabbit serum for the Neufeld reaction should be tested with all types and only specific serum should be issued.

The Neufeld reaction is the most rapid and reliable method for typing. The proper proportions of serum and sputum must be used for consistent results.

Mouse inoculation may be employed if no reaction is obtained on direct examination. Peritoneal exudate may best be typed by the Neufeld method, care being taken that very small amounts of material are used.

Cultural examination will show the relative proportions of different organisms present.

An adequate lighting system for the Neufeld reaction is essential.

Alpha Hemolytic Streptococci of Air*

Their Variant Forms, Origin and Numbers per Cubic Foot of Air in Several Types of Locations

LEON BUCHBINDER, PH.D., MATHILDE SOLOWEY, AND
MORRIS SOLOTOROVSKY

DeLamar Institute of Public Health, College of Physicians and Surgeons, Columbia University †; and W.P.A. Air Pollution Survey, Department of Health, New York, N. Y.

THIS is the second report on the study of bacteria in the air of several types of locations in New York City. The first, a brief preliminary note,¹ was read before this section in 1936.

The previous report summarized the findings as to average numbers of total bacteria and of alpha and beta streptococci, in 6 types of locations, during the first 16 weeks of the study. The present paper continues and elaborates the analysis of the findings, as to alpha streptococci, only, for an entire calendar year. The probable origin of the alpha streptococci found is also discussed, as well as the appearance, numerical frequency, and possible significance of certain variant forms.

THE NUMBER OF ALPHA STREPTOCOCCI IN THE AIR AT THE SEVERAL TYPES OF LOCATIONS

A total of 2,517 samples of air were examined by means of the Wells Air Centrifuge in sheep's blood agar cultures for the presence of alpha hemolytic streptococci. The samples were from sources distributed as follows: 6 schools, 46 per cent, the cars of a subway, 20 per cent, and 6 theatres, 6 streets, and a park, 34 per cent. The findings are presented in Table I.

Table I indicates that more streptococci were found in schools than in any other location, as evidenced both by the total number per cu. ft. and the percentage of positive samples. The subway was a close second in number of positive samples obtained, but the average number of streptococci for all samples in the subway was proportionately lower. Streets, non-air conditioned theatres, air-conditioned theatres, and the park followed in decreasing order as indicated.

The findings in the 6 schools are analyzed further in Table II according

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

† Supported by a grant from the John B. Pierce Foundation.

NOTE: Most of the laboratory studies reported herein, were performed at the DeLamar Institute, while the routine collection of air samples was made by the Air Pollution Survey, a W.P.A. project sponsored by the Department of Health.

TABLE I

Alpha Hemolytic Streptococci per Cu. Ft. of Air at Several Types of Locations in New York City Studied for a Period of One Year

(Samples on Sheep's Blood Agar)

Location	No. of Samples	No. Cu. Ft. of Air Sampled	No. of Strep. Isolated	Av. No. Strep. per Cu. Ft. Air All Samples	Per cent Positive Samples	Av. No. Strep. per Cu. Ft. Air Positive Samples Only
All	2,517	36,080	4,015	0.08	48	0.16
Schools	1,164	17,232	2,511	0.15	68	0.22

Central Park	129	1,529	51	0.03	25	0.14

to the individual school sampled. The first point of interest is that the schools fall into two distinct groups. Schools numbers 1 to 3 have higher average numbers of streptococci per cu. ft. of air for all samples and for positive samples, as well as a greater percentage of positive samples, than do schools 4 to 6.

Schools 1 and 2 are 2 of the oldest in the city and are in the lower east side. They are of definitely inferior construction, contain small rooms, and are difficult to keep clean, number 1

being the poorer of the 2. It may also be of interest that the children are of the lowest economic group in the city, and come from a health area which shows a high incidence of reportable communicable disease. Schools 5 and 6, the 2 high schools in the group, are located in the upper middle west side. While of more modern construction than the first 2 schools they cannot be called new. They are of more suitable design than the former, however, since they have large rooms, large windows, and high ceilings. These

* Averages

2 high schools can be rated as the best in the group in general appearance. School 6, moreover, is the only one of the 6 which uses a mechanical system of ventilation. Schools 3 and 4, in the upper east side, are of about the same age as the 2 high schools, but their type of construction is less modern. School 4 has better facilities for natural ventilation and appears to be somewhat cleaner than school 3. The pupils of school 4 are derived from a higher economic group than those of the other 5 schools.

Three types of enclosed spaces have been sampled in each school—classrooms; assembly rooms such as playrooms, lunch rooms and gymnasias; and corridors. The classrooms were tested while they were occupied, within 1 hour after they had been vacated ("Just Vacated") and after longer periods of vacancy ("Vacant"). The assembly rooms were studied both occupied and vacant. The findings are listed in Table III. The values for the average number of streptococci per positive sample for all schools indicate

that occupied assembly rooms had most alpha streptococci, followed by occupied classrooms, corridors, just vacated classrooms, vacant assembly rooms, and vacant classrooms in the order named. The sequence of percentage of positive samples is practically identical. When the findings for each school are examined separately the differences between the two groups of schools noted above (1 to 3 and 4 to 6) hold almost constant throughout the 6 conditions.

THE ORIGIN OF ALPHA STREPTOCOCCI OF AIR

In an attempt to determine the origin of air streptococci more than 2,000 strains of alpha streptococci have been studied in detail. All cultures were classified into the 8 species of the Holman system and in addition were examined for their microscopic morphology and their effect on litmus milk.

The results indicate that the probable origin of most of the air streptococci is the human throat.

Results—The distribution in the Holman system of cultures from the

several types of locations is given by both total numbers and percentages in Table IV. It is noted that 83.2 per cent of cultures from all locations fall into the 3 species—*salivarius*, *mitis* and *ignavus*—whose presumable origin is the human nasopharynx. Likewise 9.7 per cent are *equinus* and 4.4 per cent *fecalis*, while the remaining 2.7 per cent are classified by their sugar fermentations in the 3 so-called non-hemolytic species although they all produce greening on agar. When the figures are further analyzed by the 5 types of locations sampled, it is seen that the percentage of throat strains at each type of location except streets varies between 84.3 and 87.5. The high figure for the park is probably not significant, since only 24 cultures were included. The percentage of 59.7 for street cultures, although less than that

for the other types of locations, as was to be expected, is still relatively high, in fact greater than the combined figures for *equinus* and *fecalis* (34.3 per cent). Nevertheless, if the lower percentage of streptococci of presumably nasopharyngeal origin obtained from streets is applied to the data on total counts in Table I, streets drop from 2nd or 3rd to 5th place in order of relative importance, the park alone being lower.

As was to be expected the percentage of *equinus* cultures in streets was higher (25.7) than that at any other location. The next greatest was park (9.7) and the lowest schools and theatres (7.3).

A check on the identification of strains is provided by their reaction on litmus milk as given in Table V. Only 11.5 per cent of the *salivarius* cultures

TABLE V

* *Salivarius* of Safford, Sherman and Hodge.²

(Safford, Sherman and Hodge²) failed to produce acid; 77 per cent of these were cultures (*ignavus*) which do not ferment lactose. It should be pointed out that a greater number of air cultures of presumed nasopharyngeal origin failed to coagulate milk than would be expected with strains obtained directly from human sources. That only 4.3 per cent of *equinus* cultures affected milk is in conformity with the report of Hodge and Sherman³ who observed that none of 72 recently isolated *equinus* strains studied had any effect on milk. Likewise the finding that 98.8 per cent of the *fecalis* strains fermented milk agrees well with a similar observation of Sherman, Mauer, and Stark⁴ on 434 cultures.

THE VARIANT FORMS OF ALPHA STREPTOCOCCI IN AIR

When the air sampling studies were begun there were observed in the Wells cylinders a number of suspicious pinpoint colonies which produced alpha hemolysis on blood plates but did not appear to be typical streptococci when examined microscopically after 18 hour broth culture.

Although they were Gram-positive cocci which varied in size in different cultures from small to large, as do air streptococci, they differed from the latter by appearing either as diplococcal forms, tetrads, or irregular groups of cocci, large or small. Usually one type of grouping predominated but seldom if ever was it the only one present. In addition occasional short chains comprising no more than 6 cocci were noted, but they were never predominant. Analysis of the microscopic morphology of 1,949 air strains reveals that only 39.6 per cent (771) formed typical moderate to long chains while the remaining 60.4 per cent (1,178 strains) formed predominantly pairs, tetrads, or groups of cocci.

In an attempt to arrive at an objective decision as to the identity of these aberrant strains, regarded provisionally as streptococci, two series of studies were undertaken: (1) a comparison of the biochemical and morphological properties of (a) definite alpha streptococci freshly isolated from human throats, (b) definite, and (c) putative alpha streptococci of air; (2) a comparison of the distribution of the several variant morphological types at the different locations and of the incidence of definite and putative strains of presumed nasopharyngeal origin in the several Holman species.

It was found that the aberrant organisms were probably altered streptococci.

TECHNIC ORIGIN OF CULTURES

The alpha streptococci of the throat were isolated from sheep's blood agar plates which had been streaked with routine throat swabs. They were obtained from the diagnostic laboratory of the Department of Bacteriology, College of Physicians and Surgeons. Both the definite and putative alpha air streptococci were isolated from Wells' sheep's blood agar cylinders which had been exposed in the usual places of sampling.

TESTS

The following properties were studied:

1. *Fermentation*—Brom-creosol purple meat extract broth was used, prepared according to the following formula: 0.3 per cent Liebig's meat extract, 1 per cent neopeptone, 0.5 per cent sodium chloride, and 1 per cent of the test substance. Thirty c.c. of 0.04 per cent brom-creosol purple solution were added to each liter of medium. The tests were performed by inoculating 2 drops of 18 hour broth

TABLE VI

A Comparative Study of Some Morphological and Biochemical Properties of Alpha Streptococci of the Throat and of Air, and a Group of So-called Putative Alpha Streptococci of Air

culture into 2 c.c. of the medium which had been Arnoldized on 3 successive days. Results were recorded at the end of 48 hours and 96 hours incubation at 37° C. Action on the following substances was studied: lactose, salicin, mannite, dextrose, sucrose, levulose, maltose, inulin, galactose, raffinose, arabinose, glycerine, and sorbitol.

2. *Final pH in dextrose broth cultures*—Cultures prepared as stated above were incubated for 7 days at 37° C. and then tested electrometrically by means of the glass electrode.* The pH value was calculated to the second

decimal place by reference with standard buffers of known pH, and recorded to the first decimal place.

3. *Effect on litmus milk*—Litmus milk was prepared by adding approximately 60 c.c. of litmus solution to 1 liter of defatted fresh pasteurized milk, and tubed in 2 c.c. amounts. Inoculations and readings were carried out in a manner similar to that for fermentation tests.

4. *Macroscopic and microscopic morphology and effect on blood*—All cultures were examined microscopically after 18 hour incubation in nutrient beef infusion broth (pH 7.6 to 7.8) and the relative clarity or cloudiness of the broth was recorded as well. In

*We are indebted to Dr. Theodor Rosebury of the Department of Bacteriology for the use of his glass electrode-saturated tube potentiometer.

addition pour plates of 4 per cent sheep's blood agar were prepared with each culture. Type of hemolysis was recorded after 18 hours incubation at 37° C. and after 2 additional days at room temperature as well as the translucency of the colonies and the approximate ratio of surface to sub-surface colonies.

RESULTS

1. The fermentative action of 69 throat cultures on 3 sugars, lactose, salicin and mannite, which determine 8 species of alpha streptococci in the Holman classification, indicated that all cultures fell into one of 3 species—*salivarius*, *mitis*, or *ignavus*. Accordingly, only those actual and putative air alpha streptococci which gave similar reactions with the same substances and which composed a majority of the strains were included in the comparative study. It is seen from Table VI that the largest number of strains in

each group gave the reactions of *Str. salivarius*. Further discussion of the distribution of cultures in the 3 species of Holman is of doubtful value since Safford, Sherman, and Hodge² have recently concluded that they are in reality but a single species. Over 60 per cent of the cultures in each group fermented all of the 5 sugars: dextrose, sucrose, maltose, levulose, and galactose, with the putative forms having the highest percentage (86.9). On the other hand, the putative forms acted on raffinose only seldom (16 per cent); whereas 50 per cent of throat and 40 per cent of definite air forms fermented raffinose. Fermentation of the other substances studied (not included in the table) was rare; inulin was fermented by only 10 throat strains, 5 definite and 2 putative air strains; sorbitol by 1 strain each of the 3 groups; arabinose by 5 definite air strains only and glycerin by none.

Examination of the final pH values

in glucose broth cultures reveals a distinct difference between the putative air strains on the one hand and the definite air and throat strains on the other. The greatest number of the putative air strains yielded values in the pH zone 4.8 to 5.5, while most of the definite air and throat strains yielded pH values between 4.2 and 4.7. The data on pH have been further analyzed in Figure I, where the number of cultures is plotted as ordinates and the pH zones as abscissa. The putative air streptococci for this purpose have been separated into 3 groups on the basis of predominating microscopic morphology: in group B, diplococci; in group C, tetrads; and in group D, irregular groups or clumps. The graph indicates that most of the cultures of both throat and (definite) air streptococci fall into a zone of pH from 4.1 to 5.0 with a peak in both instances occurring at 4.4 to 4.7; whereas a great majority of each of the 3 putative air forms are distributed in a zone of pH between 4.8 and 5.9 with the peak in each instance occurring between 5.2 and 5.5.

Analysis of the effect of the several groups on litmus milk confirms the impression that the putative air strains are comparatively weak acid producers, since the majority of them form insufficient acid to coagulate milk. The obvious streptococci, on the contrary, both acidify and coagulate milk. These findings confirm an impression obtained when the routine sugar fermentations were performed: that the throat and long-chained air strains form more acid than the aberrant strains, as evidenced by color difference with brom-cresol purple indicator.

It was noted that all strains after 18 hours incubation at 37° C. in poured blood agar plates produced colonies surrounded by green zones. After further incubation for 48 hours at room

temperature several distinct patterns appeared. One, most common for all 3 groups, consisted of a zone of clearing immediately adjacent to the colony and about equal in width to the diameter of the colony which usually contained some intact red cells. Surrounding this area, was a narrower discrete green halo. About a quarter of the putative strains and a few of the definite streptococci showed a diffuse rather than a discrete green zone. Two less common patterns were observed with strains of all groups: (a) adjacent to the colony a discrete green zone, then a clear zone, and finally a second green zone; and (b) a green zone without differentiation.

The surface colonies were usually smooth and were either translucent, opaque, or opaque with a white center. Most of the throat and definite air streptococci gave translucent colonies, whereas the colonies of putative strains were opaque, with or without a white center. The translucent colonies grew on the surface in smaller proportion than did the opaque ones. The inference might be made, therefore, that opaque colonies tolerate free oxygen better than translucent ones.

The study of the relative turbidity of broth cultures disclosed the well known tendency of long-chained streptococci to produce an almost clear supernatant broth. Ninety-two per cent of the putative air streptococci, on the other hand, which displayed no long-chained forms, yielded cloudy broth.

2. The distribution of the 3 variant morphological types was consistent in the several locations. Thus the figures for pairs, tetrads, and groups in schools (1,286 strains) were 25.1, 8.9, and 23.6 per cent, respectively, whereas those for all other locations (663 strains) were 26.5, 9.8, and 29.6 per cent.

The uniformity of distribution of the

TABLE VII

Comparative Distribution of Definite and Putative Streptococci of Air in the Throat Species of the Holman Classification

* Per cent of definite and putative cultures combined.

several morphological types is depicted by a different method in Table VII. The percentage distribution of cultures in the 3 throat species at both schools and the subway indicate a good correlation between the incidence of definite and putative strains.

SUMMARY

Although most properties of definite air streptococci agree well with those of throat strains, several properties of the putative strains are at variance. The putative strains are similar to those of the throat in the fermentation of lactose, salicin, mannite, dextrose, sucrose, maltose, levulose, and galactose; the last 5 are fermented more frequently by the former than by the latter. Likewise, putative strains yield the same general type of colonies and produce similar hemolysis on blood agar. There may be added as points of similarity the occasional suggestion of streptococcal morphology (a few very short chains) in some putative strains, and their consistent distribution in air similar to that of definite streptococci. Finally, attempts made in this laboratory to age putative strains in broth in order to dissociate chains of cocci from them have yielded suggestive results. Conversely, throat strains of streptococci aged in like manner have given some indications that they may

produce cocci of altered grouping. It seems justifiable, therefore, to assume that the aberrant forms are closely related to the streptococci of the throat and possibly derived from them.

If this hypothesis be accepted, one cannot help but be impressed by the marked differences between the altered and the typical streptococci. The former, besides differing microscopically, produce far less acid, seem to ferment raffinose less frequently, form opaque colonies more frequently, and are better adapted to aerobic growth. Since our experience with throat strains suggests that such variant green streptococci are rarely if ever present in the nasopharynx, and since it is difficult to believe that their normal habitat is the air, it would appear that their aberrant characteristics developed as a result of their aerial environment.

DISCUSSION

Two principal questions asked at the inception of this study were: (1) Does the presence of alpha hemolytic streptococci in air indicate human pollution thereof? (2) Can quantitative estimation of their numbers serve as an index of the degree of pollution? The first question would seem to be answered affirmatively since the results in schools, a subway, and theatres indicate that a great majority of air alpha streptococci

are probably of human nasopharyngeal origin. Comparison of several properties of a number of strains of air streptococci with those of streptococci isolated from throats reveals a high degree of correlation.

It also seems most likely that the number of alpha streptococci present in air indicates the degree of human pollution. The latter in turn is probably influenced by the extent of current or recent occupancy and the quality of ventilation. Since the conditions obtaining during routine sampling at the several types of locations could not be readily controlled it is difficult to evaluate finally the relative importance of crowding and ventilation. However, it appears that other conditions being constant the effects of ventilation are more important than those of crowding. Thus subway cars, which are grossly overcrowded at certain hours but which have adequate ventilation, had less streptococci than schoolrooms which usually provide much more air space per person but are not so well ventilated. Similarly fewer positive samples and fewer streptococci per sample were also obtained from theatres where larger numbers of persons congregate in single rooms than in schools. Here the presence of more persons appears to be compensated for by the diluting effect of a large air space which in addition is supplemented by an almost constant influx of fresh air. Incidentally the smaller percentage of positive samples in air conditioned as compared to non-air conditioned theatres might also be regarded as an expression of better ventilation.

It is obvious that, in the absence of guiding precedents, it is difficult to set absolute standards of quality on the basis of the total number of alpha streptococci in air. It is not so difficult, however, to assess the fact that the schools studied had far more strep-

tococci per available unit of space than any other type of location; or that certain schools, which had the highest index of streptococci, also were the oldest and the most difficult to keep clean, and were so constructed that there was a maximum of pupils in a minimum of space. These findings were in schools all of which were relatively old. Newer schools, with better ventilation, would probably show better conditions.

It is apparent that a majority of alpha streptococci of air have become altered in morphology and physiology. In experiments not recorded above it was found that a sweeping of unoccupied schoolrooms immediately before taking air samples resulted on the average in a twofold increase of the alpha streptococci of air. It seems clear, therefore, that the normal air flora of occupied rooms must include streptococci of both recent and remote human origin. These findings suggest that respiratory pathogens cast into air may likewise persist and become altered. Indeed it has been shown by White⁵ that beta hemolytic streptococci can be obtained from the air of unoccupied hospital rooms by sweeping their floors as long as 2 weeks after the removal of patients suffering from puerperal fever. Likewise Brown and Allison⁶ recently found that hemolytic streptococci can be isolated with relative ease from scarlet fever wards. These authors observed that the greatest numbers of organisms were found in the morning hours due to the various morning activities such as sweeping, cleaning, making of beds, etc. These persistent forms may be regarded as potential pathogens, but to what degree they may have been altered by their aerial environment is not known.

The nature and significance of such aerial changes, if they occur, with particular reference to possible epidemio-

logical effects, are questions for further study. Work is now in progress in which under controlled conditions of temperature, humidity, light, ionization, etc., it is hoped to ascertain not only the lethal but also the debilitating action of air on organisms artificially sown therein.

SUMMARY

Streptococci of the alpha hemolytic types were found to be widely distributed in the air both of enclosed places of congregation and of the open spaces of a large city. A large majority of these organisms seemed to be of nasopharyngeal origin. Many of the strains, of presumed nasopharyngeal origin, differed in morphology and certain biochemical properties from typical alpha streptococci of the throat. It is suggested that these differences are due to the effects of aerial environment. The possibility of similar alterations in respiratory pathogens is discussed.

Alpha hemolytic streptococci were present most frequently and in greatest numbers in the air of school buildings, and an apparent relationship was noted between the type of room and degree of occupancy and the numbers found, the largest numbers being found in occupied assembly and classrooms.

The quantitative distribution of streptococci in the other types of locations may be listed in a descending order as follows: Subway, non-air conditioned theatres, air-conditioned theatres, streets and park.

An attempt is made to associate the differences in streptococcal content of the several types of enclosed places, as well as in the individual schools, with their varied facilities for ventilation.

ACKNOWLEDGMENTS—It is a pleasure to record our indebtedness to Professor Earle B. Phelps, who inspired these studies, for his constant advice and encouragement. We also wish to acknowledge with thanks the interest of and assistance given by Deputy Commissioner of Health Sol Pincus, who was in charge of the Air Pollution Survey. Finally, the fine coöperation of Harry R. Saint, Project Engineer, A. C. Stern, Superintendent, and other members of the W.P.A. administrative staff deserves our appreciation.

Nutrition and Dental Caries*

BION R. EAST, D.D.S.

Technical Consultant, Vitex Laboratories, Inc., Harrison, N. J.

DIFFERENCES of opinion exist regarding the etiology of dental caries. Some insist that one type of bacteria is the cause of this disease which universally affects man; affecting him apparently, in direct proportion to the degree of his civilization. Others advance faulty oral hygiene, endocrinology, malformation, genetics, or malnutrition as the cause. Probably all these, and possibly other factors play a rôle. The neglect of any one factor during an investigation may lead to faulty conclusions.

The slogan "A clean tooth never decays" has been drummed into a believing public by some of the dental profession and commercial interests. Millions of dollars are spent annually for tooth brushes, dentifrices, and mouthwashes, but the incidence of dental caries keeps apace among our population at large.

The immediate cause of dental caries, when found, will probably be simple, and it will, when discovered, be of great interest. But from the public health standpoint, the pressing question is what can be done to help alleviate the condition at present.

A review of the literature discloses few reports presenting valid data on this subject. Many papers are disregarded here because they present: (1)

simply opinion; (2) the numbers in the experiment were too small to give significant results; (3) proper control was not exercised; (4) more than one variable was used in the same experiment; (5) when a vitamin (particularly vitamin D) has been studied, an assay of material was not made, therefore the potency of the material was unknown; and (6) vitamins D of different sources (vegetable and animal) have been considered as being identical.

After subjecting published studies to these tests, few investigations made on humans need analysis. Studies of children as outpatients are disregarded here because of the difficulties of imposing control. Animal experimentation is also disregarded because the final test of anti-caries control in humans should be controlled human experiments.

One study, that of Bunting, et al.,¹ is of particular significance because under controlled conditions 493 children, located in two orphanages, were used to determine the caries preventing and arresting properties of an institutional diet with and without the use of an antiseptic mouthwash, and that of an improved diet with and without the mouthwash. The study covered 2 years.

Figure 1 demonstrates the reported results. Those fed the improved diet with or without the mouthwash had practically the same results. The institutional (unimproved) diet groups—with or without the mouthwash had more new cavities and more active

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

caries than those on the improved diets with or without the mouthwash.

The group fed the institutional diet with the mouthwash had more new caries and more active caries than the group fed the same diet without the mouthwash. One might deduct from this experiment that the mouthwash was caries-inducing. The significant results are the marked reduction in new caries in the groups which were fed the "well-balanced well-fortified" diet. This improved diet had as its base one quart of milk per day, with green vegetables and fruits. The improved or experimental diet was substantially that recommended by Boyd and Drain except that no added vitamin D was given.

McBeath^{2,3} reported studies to determine the caries preventing properties of diets. His investigations were made in orphanages in and about New York City. He noted that improving the diets resulted in a marked decrease in new carious tooth surfaces. He also observed that the dietary factor which

was usually most deficient in an otherwise well balanced, easily obtainable diet was vitamin D. He reports significant success in caries control when various amounts of vitamin D are added to the diets.

Mellanby⁴ and Anderson⁵ have reported likewise.

In Figure 2 are shown some of McBeath's results. There is a definite decrease in the caries incidence in the groups receiving the diets with added vitamin D. The studies of the years 1930-1931 and 1931-1932 are particularly interesting because the same individuals used as experimentals were controls in the previous or the following year. The groups were reversed and the caries incidence was likewise reversed.

In 1934 McBeath⁶ reported the caries inhibiting properties of graded amounts of vitamin D when given as vitamin D milk. The vitamin D milk supplemented the institutional or control diet. The results in caries control achieved with the experimental diets

are contrasted with those on the control diets. The caries inhibition was in direct proportion to the amount of vitamin D given. The anti-caries effect of direct exposure of the skin to ultra-violet light was also demonstrated.

Since the publication of the McBeath 1933-1934 work, McBeath and Zucker⁷ made further analyses of the data collected during the 3 year investigation. Through the extreme courtesy of the authors the data, in part, are here presented before publication.

In all, over 800 children were observed. The children ranged in age from 8 to 14 years. They were about equally divided according to sex. They were all resident during the complete study period of orphanages where control could be established and maintained.

A notable contribution is observations of the incidence of caries during various seasons of the year. There is apparently a marked seasonable response. The period designated as autumn-winter covers about 100 days

from the autumn examination. The winter-spring period ranges from the mid-winter examination to spring. Autumn-spring is a combination of the two periods.

In Figure 3 is shown the mean increase in carious surfaces per 100 days per mouth of controls observed over a complete calendar year and examined at various intervals. The highest incidence is during that period most remote from the summer.

In Figure 4, the seasonal response is again demonstrated together with the caries inhibiting influence of various amounts of vitamin D in the form of vitamin D milk. A like response was demonstrated when the skins were exposed to ultra-violet light.

Boyd and Drain of Iowa have reported observations of dental caries control over a period of years since 1928.^{8,9} Their data will not be discussed at length here. Their criterion has been the arrest of established dental caries rather than prevention of primary lesions involving the enamel.

They studied dentinal rather than enamel caries. This has led to confusion where the difference has not been appreciated by critics.

In brief, Boyd and Drain report that a well rounded diet, when actually consumed by normal children, will arrest established caries. The recommended

diet is simple. It consists of the following essentials:

- 1 quart of milk per day
- 1 egg
- 1 ounce of butter
- 1 teaspoonful of cod liver oil (the year around)
- 2 vegetables (one being raw)
- Fresh fruits

Candy is not prohibited *after* meals. In groups under well controlled conditions, where the consumption of the food was definitely known, arrest took place in 10 weeks' time. The "activity of caries was determined on the basis of the permeability of the exposed dentine to the exploring tine; if at all permeable the decay was considered active."

Recently, Boyd, Drain, and Stearns¹⁰ reported a hospital controlled balance study on a small group of children from 3 to 6 years of age. The study covered 7 months. The individuals were fed in succession 4 diets. The principal difference in these 4 diets was the amount of vitamin D fed.

The children had active caries of the dentine. The criterion was activity of caries. During the 1st period, the children were continued (in the hospital) on the orphanage diet; during the 2nd the hospital diet except no added vitamin D was given; during the 3rd, irradiated milk with 155 units of vitamin D was substituted for the plain milk previously fed. Following these 3 periods the authors state: "For many weeks status was virtually stationary with minimal but definite activity, even after the children had received a diet of high protective value aside from its vitamin D content for 5 months."

During the 4th and final period, the children were continued on the same diet except the vitamin D content which was increased to 600 U.S.P. units per day in the form of cod liver oil. In this final study period after 9 weeks,

the results were: "The caries was finally adjudged arrested and this was confirmed by subsequent examination."

SUMMARY

1. Improving the diets of children living under controlled conditions seems to lessen the occurrence of caries. These results seem uninfluenced by the use of an antiseptic mouthwash.

2. The seasons seem to affect the appearance of caries—that period most remote from summer having the greatest incidence.

3. Vitamin D seems to play an important rôle in seasonable caries occurrence; its presence in the body either as a result of direct exposure of the skin to ultra-violet light or by its inclusion in the diet, tends to lessen the seasonable variation.

4. A diet which is caries inhibiting without added vitamin D becomes more inhibiting when vitamin D is added either as cod liver oil or as vitamin D milk.

EDITORIAL BOARD

(Names to be announced)

VINSON-BARKLEY BILL

AMONG the resolutions adopted at the Association's 66th Annual Meeting in New York City during the week of October 4 was one supporting the Vinson-Barkley bill (H.R. 2711) as providing the best procedure and organization for lessening the danger to public health from stream pollution. This proposed federal legislation was passed by the House of Representatives on April 21 and by the Senate in amended form on August 16. The first session of the 75th Congress came to an end before agreement was reached by the House and Senate Conferees appointed to reconcile the differences in the bill as passed by the two Houses of Congress. Further consideration of a compromise agreement by the Conferees awaits the reconvening of the 75th Congress, either in the special session convened November 15 or in the regular second session in January, 1938.

The previous history of the Vinson-Barkley bill which will grant to the United States Public Health Service enlarged responsibilities and duties for coöperation with the states in water pollution control is of interest. The original bill was prepared and sponsored by the Committee on Stream Pollution of the Cincinnati Chamber of Commerce in January, 1936. Hearings were held by the Committee on Rivers and Harbors of the House of Representatives and by a sub-committee of the Committee on Commerce of the United States Senate on May 20 and 21, 1936, respectively. These committees of the 74th Congress reported out a substitute bill recommended by the Conference of State and Territorial Health Officers which was acceptable to the sponsors of the original bill. Before the adjournment of the 74th Congress in June, 1936, the bill had passed both the House and the Senate, but did not become law as it was delayed for reconsideration in the Senate, which was not reached before adjournment. Reintroduction in the 75th Congress has placed the proposed federal water pollution control legislation at a point where its fate depends to a great extent upon the action of the House and Senate Conferees when Congress next convenes.

The Vinson-Barkley bill as passed by the House of Representatives provides for federal water pollution control in accordance with principles which have led to success in other federal aid projects, which are as follows: (1) The stream pollution program is turned over to a long established federal agency in a regular

government department under trained career personnel who have had years of experience in working with state and local officials. (2) The federal government does not attempt to do the work of controlling stream pollution as actual abatement work will be done by the states, with the full coöperation and encouragement of the federal government. (3) The main basic principle is the matching of federal funds with states and municipalities, and the loaning of funds to state, municipalities, and industries for remedial treatment works involving financial participation and responsibility for the actual construction by the state and local agencies. (4) Funds are furnished the states through allotments to the state health authority for the maintenance of a continuous program of promotion, investigation, and planning.

The more important changes proposed in the Vinson-Barkley bill by the amendments added in the Senate are (1) granting of the consent of Congress for two or more states to enter into agreements or compacts for the abatement of water pollution, (2) classification of the navigable waters of the United States by watershed districts, (3) making of industrial polluters of navigable waters eligible for federal grants-in-aid for the construction of remedial treatment works, (4) establishment of limiting requirements for polluting material and for the extent of treatment needed in such navigable water districts, and (5) provisions for action in the federal courts for the abatement of water pollution when constituting a public or common nuisance as defined in the amended bill.

The acceptance of these amendments by the House of Representatives would make the bill more satisfactory to those groups favoring centralized governmental control of water pollution as contrasted with the views of its original proponents who advocate the principle of coöperation of the federal government for improved state control. These amendments would modify the two essential elements of the Vinson-Barkley bill necessary for constructive work in stream pollution control, which are (1) the strengthening of the state organizations so as to be able to respond to public demand for adequate enforcement of state laws and regulations, and (2) the availability of federal funds for loans and grants to states and municipalities, and loans to industry for stream pollution abatement.

Friends of the original Vinson-Barkley bill are reported to be of the opinion that the whole effort is likely to be lost unless the original bill without substantial modification is reported back to the Senate by the House and Senate Conferees. Acceptance by the House of Representatives of the amended bill as passed by the Senate is doubtful, for the House appears committed definitely to the principle of state control and abatement of water pollution. Moreover, there is serious question as to the constitutionality of federal court action in water pollution matters.

Members of the public health profession, who have definite views on the merits of state and federal control of stream pollution, would serve a useful public service by communicating their views to the House and Senate Conferees as it is quite likely that the bill will receive their attention as soon as Congress convenes. The House Conferees are headed by the Honorable Joseph J. Mansfield of Texas, Chairman of the House Committee on Rivers and Harbors. The Honorable Royal S. Copeland, United States Senator from New York and Chairman of the Senate Committee on Commerce is the ranking Senate Conferee. It would be unfortunate, to say the least, if this important and constructive federal legislation should fail at this time.

It is no exaggeration to estimate conservatively that the future abatement of water pollution on a broad comprehensive scale will be retarded by a decade or more if this meritorious legislation does not become law at this time.

STANDARD BIRTH AND DEATH CERTIFICATES

THE Bureau of the Census has sent out, within the last month, a set of three questionnaires, to obtain an expression of opinion on revision of the Standard Birth and Death Certificates and on the desirability of setting up a Standard Stillbirth Certificate. The questionnaires have been sent to public health agencies, county medical societies, specialized medical associations, schools of hygiene and public health, and many other organizations and individuals interested in public health and the collection of vital statistics. This represents a unique opportunity, to those in public health work, to have a part in the determination of what material is to be collected in vital statistics for the decennial period 1940-1950.

Upon the return of these opinions, a careful analysis is proposed by the Bureau of the Census, to be used as the basis for making up a set of preliminary forms. These preliminary schedules will then be sent to the various public health organizations for criticism and comment. After revision the new Standard Certificates will be recommended to the states for universal adoption for the next decade.

The major problems involved in revision of the present certificates are: improvement of the cause of death information, completeness on place of residence, determination of the need for a Standard Stillbirth Certificate, and simplification of the certificates without the elimination of desirable supplemental information.

There are many objections to the present statement, on the death certificate, of the cause of death questions. The chief objections arise from the difficulty in determining "primary cause of death." This difficulty is partly due to the lack of a time sequence for multiple causes. A definite time sequence would be of material assistance in determining the actual cause of death.

In reporting residence there has been some confusion among the doctors and others filling out the certificates. The confusion has arisen in differentiation of place of death or birth and place of residence. Many suggestions have been made to remedy this situation, among them one which would ask place of birth or death and residence in parallel columns with the same information for each.

The need for a stillbirth certificate has been discussed widely at meetings of the American Public Health Association and recommended by its sub-committees for adoption as one of the standard certificates.

The questionnaires suggest simplification of the birth and death certificates by placing only the basic legal information on the face and collecting important supplemental data, applying to but one cause or group of causes of death, on the back or on a supplemental schedule. The attention of those interested is directed to this important item on the questionnaire.

In view of the wide clearance being attempted, it is urged that all those interested in vital statistics and public health work send in their opinions promptly on the forms provided or write to the Bureau of the Census for a set of questionnaires.

PUBLIC HEALTH EDUCATION*

To Librarians, Research Workers, Students, and Health Education Workers:

In earlier years the annual index to the *American Journal of Public Health* carried no references to this "Education and Publicity" or "Public Health Education" department in the *Journal*.

This paragraph then supplements the index: starting with July, 1923, the department will be found in all issues, except in two of 1924, and one each in 1929 and 1935.

Children Have the Last Word—

In England, according to the school medical officer of West Riding,

"dental propaganda might well be concentrated on the children themselves, rather than on the parents . . .

"The last word as to whether a child will accept dental treatment remains with the child in a majority of cases" says one member of the dental staff.

"The difficulty is probably not solely due to lack of parental control. There is a persistent tendency to regard dentistry merely as a service for the relief of pain and for purely cosmetic purposes."

In *Mother and Child*, 5, Tavistock Sq., London, W.C.1, England. Nov., 1937. 9d.

A Significant Amalgamation—

Of great importance in the school health field is the step described in the following selected paragraphs:

On the 28th of June, the American Physical Education Association and the Department of School Health and Physical Education of the National Education Association were officially amalgamated to form the American Association for Health and Physical Education—a Department of the National Education Association. This merger (seeks) . . . to unite the efforts of health educators,

physical educators, and leaders in school recreation under one organization. . . .

The reorganization carried over the larger part of the organization of the American Physical Education Association, with some changes and additions. The officers elected by the A.P.E.A. at the New York meeting were continued, as were the Governing Board and the Legislative Council. Three *divisions* were added: the Division of Health Education, the Division of Physical Education, and the Division of Recreation . . . four new sections were added under the Division of Health Education, as follows: (1) Health Education Teacher Training Section, Dr. C. E. Turner, Massachusetts Institute of Technology, Chairman; (2) School Physicians Section, Dr. Don W. Gudakunst, Department of Health, Detroit, Chairman; (3) School Nurses Section, Lulu V. Cline, South Bend, Ind., Chairman; and (4) Nutrition Section, Carlotta Greer, Cleveland, Chairman. These sections, with the Health Instruction Section with Major E. V. Graves of the State Department of Education, Virginia, as Chairman, form the Health Education Division under the chairmanship of Dr. Edna W. Bailey of the University of California, Berkeley, the immediate Past-President of the Department of School Health and Physical Education of the N.E.A. . . .

The new Association will continue to publish the *Journal of Health and Physical Education* and *The Research Quarterly*, and will carry on the work in physical education that was done in the past by the A.P.E.A. In addition, however, the American Association for Health and Physical Education assumes new and profoundly important tasks. First, the Association, through the Division of

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Health Education, hopes to give unity and leadership to much of the work in health education as it affects the school. To this end—just as the A.P.E.A. did and the new Association will continue to do with physical education national professional organizations—national organizations in the field of health education that are desirous of coöperating, are invited to become affiliated organizations, to have a voice in the Legislative Council, and to participate as organizations and as individuals in our work, our deliberations, our legislation, and our conventions—state, district, and national. In addition, we are hopeful that the experts in all fields of health education will coöperate with the Association in furthering the service to be rendered by the Association, without in any way lessening or limiting their services as individuals or through other professional organizations through which they have been accustomed to work. . . .

The merging with the National Education Association affects the Association most favorably. No limiting restrictions have been imposed. The same state, district, and national organizations and meetings will be continued and expanded to include health education and recreation in each constituent organization of the Association. In addition, the organized forces of the National Education Association will be at the service of the American Association for Health and Physical Education in every way possible. . . .

In *Journal of Health and Physical Education*, Ann Arbor, Mich. Sept., 1937. 35 cents.

Again the March of Time—Any new "March of Time" with a health episode is a health education event of nearly world-wide significance. Shown in 7,847 theatres in the United States, just beginning in Canada, and in 3,227 theatres in other countries, we may assume that no other health education material reaches so widespread a popular audience.

Issue 4, volume 4, first released Nov. 26, 1937, carries "The Human Heart." The official synopsis is as follows:

Outstanding in this issue is another of those episodes dealing scientifically, but in layman's terms, with medical subjects for which The March of Time rapidly is becoming famous. In this instance the subject is

heart disease—ailments of the heart and circulatory system. Only recently The March of Time was awarded the Clement Cleveland Medal of the American Society for the Control of Cancer in recognition of "the year's most effective contribution to cancer control"—an episode in a recent release called "Conquering Cancer."

There are several—to the layman—startling facts developed by pictures, charts and statistics in the present episode on heart disease. That heart disease leads the national death rate comes as something of a shock to the average man: 449,844 deaths in 1935, more than three times the fatalities attributed to cancer, which holds second place. Astonishing, although seemingly somewhat ironic, is the suggestion advanced by some specialists that the position held by heart disease as the U. S. No. 1 killer may really be due to beneficent causes, since thousands who might once have died young, now live to a ripe old age to succumb eventually to simple deterioration of the heart.

Greatest progress, however, has been made in controlling heart ailments of children. The familiar and once-neglected "growing pains" are now diagnosed as a symptom of rheumatic fever, menace to youthful hearts. The March of Time shows how science is treating children with crippled hearts, teaching them "a new way of life," so that they can face a future not of pain and sudden death, but a comfortable and confident life.

An extensive "Clip and Work Sheet," going to individual exhibitors, suggests ways of promoting local interest in the picture, including the coöperation of medical, health, and many other groups. A variety of advertising materials is supplied. The net result will be not only large audiences for the picture wherever shown, but also that millions will read in the advertising some of the pertinent facts. Truly "Time Marches On" for health education.

A Junior Board of Directors—The E.C.D. against tuberculosis among high school students started the idea out in Indiana.

The trend in modern education to encourage student participation and self direction may offer us new pathways to the problem.

One educator says: "The most hopeful development in student activities is the encouragement given them by intelligent and informed community leaders on the problems of today and the environment in which they live." He recommends that these young people be initiated into the skills and attitudes of adult life.

Why not encourage active participation in the tuberculosis program? Why not devise some method through which they can express themselves and evolve practices that will lead to action?

Schools and teachers are coöperating to the full. The tuberculosis association itself needs closer relations with the students. Board members are prominent and experienced in life. There is no representation of the 'teen age group.

Our horizon must be broadened to include this group, so why not a Junior Board? The conclusion reached by the St. Joseph County Anti-Tuberculosis League was such as to create such an organization by asking each one of the fifteen senior high schools to appoint, elect, or select in some manner one junior and one senior to represent that high school.

The superintendents of schools and high school principals were personally consulted regarding the advisability of such procedure, and we were highly gratified by their responsiveness. They gave it their unanimous endorsement and agreed that it was a constructive project from the standpoint of the schools.

What definite duties could be assigned to that body was the next question. A survey of present activities showed enough weak spots to offer an immediate solution to this problem.

The article lists the activities, and the reasons for seeking student responsibility for them, including state health poster contest, Christmas Seal newspaper, tuberculin tests, entertainments at the County Tuberculosis Sanatorium.

In its brief existence of 2 months the junior board has scored several times. In one direction:

Eighty-five per cent of St. Joseph County's high school seniors received tuberculin tests this year—with 4 high schools 100 per cent.

Then there was publicity.

From the standpoint of publicity alone the Junior Board has proved itself an asset to the Tuberculosis League. The two local newspapers as well as every high school publication have considered the organization of the Junior Board and its activities front page news. As one board member expressed it: "We found ourselves splashed all over the front page of the *Hi-Times*." Interviewed by their classmates and called upon for stories, the students have given the Tuberculosis League and its program wider publicity than it had ever before experienced.

Told by Irma Collmer, St. Joseph County Anti-Tuberculosis League. South Bend, Ind., in *Hoosier Health Herald*, 130 E. Washington St., Indianapolis, Ind. Nov., 1937.

"Any Number of Wives"—Lango, Uganda Protectorate, won a silver-mounted wall plaque for its share in Empire Baby Week. The response to infant welfare clinics led to a maternity and child welfare section of a health exhibition at Lira.

Prior to the occasion, publicity was arranged by circularizing the chiefs, by posters and propaganda at dispensaries and clinics throughout the district, and by a tour of the chief's headquarters by an assistant district commissioner about a fortnight previous to the show. The principal bait to lure mothers to Lira was a daily baby show on the first four days of the show. On one other day there was a competition for the healthiest family group consisting of a father with any number of wives and a quota of at least three children. The *bona fides* of each party had to be certified by the village chief. The baby shows were enormously popular, some mothers walking fifteen miles to attend. As they arrived, the mothers and babies were taken to a large hut built specially for the baby show and judging. This "baby banda" was reached by passing through a plot containing a model family dwelling. On leaving the baby show the people were directed through another plot containing a model maternity hut, showing the sanitary conditions that could be achieved for a confinement in a native hut. All the accessories were hygienic and efficient, but cheap. The baby's bath was a large gourd in a wooden frame.

Of particular interest was a kind of mannequin parade of hygienic dress for women. Lango women have only recently taken to wearing any clothes, and their tendency is to copy the clothing of the Baganda, which, though extremely graceful in their country, is not so well adapted to the needs of the Lango women, who spend much of their time on their knees grinding millet. A lady skilled in dressmaking was approached and produced several very attractive garments well calculated to suit the women's needs. The dresses were backless (as babies are carried on the backs and tend to soil the clothing), and were designed to allow easy accessibility to the breasts to facilitate suckling (it must be remembered that the ordinary Lango woman spends most of her adult life suckling a baby); other features of the "models" were short sleeves, short skirts, cheapness and adaptability to the figure, as the average Lango woman has a child once a year. The garments were available at from 1s. to 2s. at the local Indian bazaar. It is estimated that 50,000 natives attended the show during the whole period. The primary lesson stressed by the exhibits was the importance of good housing, and actual houses of a sanitary and enduring type were shown in course of construction. It is doubtful whether a health show has ever been arranged for people more primitive than the Lango. They are, however, making great strides toward improved methods of living.

In *Mother and Child*, 5, Tavistock Sq., London, W.C.1, England. Nov., 1937. 9d.

Workers Health Education—Studies in occupational disease, the effects of working conditions upon the workers, and provision of health education services are primary aims of the Medical Research Institute of United Auto Workers of America, organized in Detroit (Dr. E. R. Hayhurst, part-time Advisory Director).

Health education includes the preparation of educational material for distribution to locals and to shops, and provision of a consultation and educational service to shop stewards and locals who wish to use information for the improvement of working conditions.

In "New Vista in Detroit," by S.

Kellman. *Social Work Today*, 6 E. 46th St., New York, N. Y. Dec., 1937. 15 cents.

"Your Health" Continues—The current radio program of the American Medical Association is a threefold project. There are the weekly broadcasts; the monthly articles, and supplementary teaching material in *Hygeia*; and "Your Health: Pupil's Workbook and Guide." Large pages; outline for a self-appraisal and activities under each weekly topic; many blanks in which to write answers to questions; reading references, usually including page numbers. The weak point is the bibliography. Here are 53 titles, with authors, publishers, and dates. There are no prices or page numbers, and no indication of the contents, no suggestion as to what students or teachers are to do about the list. Not all of the references attached to the weekly units are to be found in this long list at the end.

Included are "Two to Six—Suggestions for Parents of Young Children," and "The Child From One to Six." One was published in 1933, the other in 1931. Shall teacher, or student, or school librarian choose "Two to Six" or "One to Six"? Shall we choose 1933 or 1931? And where would either volume fit into the broadcasting program? *Unhappily this bibliography follows precedent. We hope that a new precedent for health bibliographies will evolve from the pattern set by the American Child Health Association.*

Published by Johnson Publishing Co., 381 Fourth Ave., New York, N. Y. No price stated.

The broadcasts are booked for Wednesdays, 2:00 to 2:30 p.m., eastern standard time, over Red Network of N.B.C.

Contagious Diseases

January 5—Sneezes and Sniffles: Cause, spread, prevention of colds, pneumonia and

influenza; importance of early medical care.

January 12—Scarlet Fever, Measles and Whooping Cough: Modern attitudes toward these diseases; their prevention by community coöperation.

January 19—Smallpox and Diphtheria: Unnecessary diseases; preventable by immunization of infants.

January 26—Poliomyelitis: Information about the disease; coöperation with President's Birthday Ball.

Preventing Future Illness

February 2—Rheumatism and Arthritis: Known factors in the causation of arthritis and its care.

February 9—Healthy Hearts and Arteries: Known ways of protecting the heart against infection and hygienic abuse; how to live with heart disease.

February 16—Don't Fear Cancer—Fight It: Known factors in the cause, prevention and treatment of cancer.

February 23—Overcoming Diabetes: Individual efforts plus medical aid will win against diabetes.

Public Health

March 2—Water, Waste, and Sanitation: Importance of community control of water supplies, sewage disposal and general sanitary matters.

March 9—Protecting Perishable Foods: What the community can and must do to protect fresh foods such as fish, fruits, vegetables, meats, bakery goods.

March 16—Keeping Books on Health: The meaning and the importance of vital statistics, contagious disease reporting and community health records.

March 23—Catching Disease from Animals: Rabbit fever, rabies, undulant fever and similar infections, and what can be done about them.

"Ye Greate Stinking Poisonous Weed"—Quoted from the *New Haven Town Records*, May 23, 1653, this phrase is supposed to refer to the ragweed of 1937. And in 1937, as in 1653, the citizen of New Haven was urged in a well written statement to eradicate the "weed which grows against his own ground." In *Health*, New Haven Dept. of Health, Aug., 1937. Old records and old newspaper files may provide texts for any health agency.

Emphasis on the extending range of ragweed is given in "War on Ragweed," by H. B. Anderson. *Health*, Toronto, Ont. Sept., 1937.

That ragweed "is the cause of approximately 80 per cent of all cases" of hay fever is not recognized widely enough.

A School Safety Display—How DeWitt Clinton High School, New York City, put on a safety exhibition is described, with 5 large pictures, in "Visualizing Safety Education," by E. H. Hastings. *Journal of Health and Physical Education*, Ann Arbor, Mich. Nov., 1937. 35 cents.

It was hoped that the exhibit would serve a threefold purpose: first, to bring home the need for safety education; second, to demonstrate graphically safety practices; and third, to indicate the interaction between school and community organizations in making America safety conscious.

Our exhibit was a coöperative affair. Teachers and students drew the preliminary plans. Pupils selected aspects of safety education for individual study. A large committee of students served as receptionists, guides, curators, and handymen. The exhibit was held in one of our gymnasiums. Popular and community interest was so high that the exhibition hours were rearranged to give all parents who so desired an opportunity to attend.

Our hygiene students contributed an array of posters, notebooks, soap models, and original photographs. The chemistry department assisted with an exhibit on drugs and explosives. The general science department snooped around the rooms and corridors, exposed Petri dishes, and showed cultures grown from bacteria picked up on these jaunts. An excellent photographic study of safety devices in use throughout the school was submitted by the physics department.

The school custodian dramatized school and pool sanitation. Students in the art department built a miniature city. The city had skyscrapers, a model business district, and suburban homes complete even to the flower gardens. Miniature autos and pedestrians indicated traffic problems. Safety placards were very much in evidence.

The city police department had a giant display which occupied an entire section of the gymnasium. Pictures, posters, and a con-

tinuous movie reinforced their plea for safety. Two officers were on hand all through the week to lecture on traffic rules and regulations. So well did they do their task that by the end of the week not only had they befriended 6,000 boys, but they had put their message across!

Space does not permit proper mention of all the exhibits. Foreign safety posters added a colorful, thought provoking note. The American Red Cross showed safety devices for water and land. Many other organizations helped.

After our exhibits had been properly mounted, we threw the gymnasium open to students, teachers, and outside visitors. Hygiene, civics, English, and general science classes attended under the guidance of their teachers. Each pupil was asked to comment briefly on the particular exhibit which pleased him most. He was also asked to make an inventory of safety hazards encountered in his own environment. This last assignment proved to be as much of an education to our teachers as it did to the pupils. Our teachers tended to think of safety in such vague terms as street safety, or home safety. Our students were much more specific. Fire, electricity, swimming, flies, sanitation, vehicles, camp, were a few of the topics our boys covered. As a final step, a committee of boys and teachers made a survey of safety hazards in Clinton. Their report was mimeographed and posted in each room.

When You Get to New York—When you plan visits to 50 West 50th Street, where the national health agencies are located in Rockefeller Center, you will wish to schedule a stop at New York Museum of Science and Industry. At least if you pass the entrance to the Museum, at the western or 6th Avenue end of the R.C.A. Building, the visible moving displays will draw you inside.

The continuous, but partly changing, displays in the Museum appeal to practically everyone. And there are examples suggestive to everyone concerned with exhibits.

The newest exhibit is the "Story of Man," built by the German Hygiene Museum at Dresden. About 100 units of "action-exhibits and dramatized dis-

plays" illustrate anatomy and physiology. Included are the following: blood circulation demonstration, cell model, embryos, additional spalteholz specimens, flow of the blood, the seat of important body functions in the brain, sleep requirements at different periods of life, organ of equilibrium, mechanism of speech, respiration in rest and motion, work distribution and assimilation in the human body, joint articulation, operation of the digestive system, mastication, cross-section book (carved and painted cross-sections of the body), gland secretion, thyroid gland, organs of the senses, and so on.

Many of the action displays, such as that of the heart which is over-size, are in continuous motion. Others can be set in motion by pressing buttons. There are devices by which each person can test for himself the soundness of his senses and the strength of his muscles. By pressing a button and placing the nose close to an aperture, you can test, for example, your ability to distinguish between such odors as flowery, fruity, putrid, and burnt. A diagram of the tongue enables you to see just where you become aware of the tastes of sweet, sour, salt, and bitter.

And of course there is a copy of the famous "transparent man."

A catalogue of the "Story of Man" exhibits will be sent upon request to the New York Museum of Science and Industry, Rockefeller Center, New York, N. Y.

Publicity Against Syphilis—The recommended anti-syphilis program to be conducted jointly in Indiana by the Medical Association and the Department of Health includes the following:

Since publicity is the essence of salesmanship, it is the opinion of this committee that a very large state-wide committee be appointed. This committee should consist of a physician duly appointed by each medical society in the state of Indiana. It should also consist of every health officer in the state. In addition to this committee, which shall be known as the "state-wide committee," sub-committees shall be appointed by

the state committee members. These sub-committees shall function in the communities in which they exist. It would be well to have in the membership of these sub-committees heads of hospitals, heads of nursing associations, social service workers, such as the head of the Community Fund, Boy Scouts, Girl Scouts, Young Hebrew Association, the Y.W.C.A., Y.M.C.A., Catholic lay organizations, etc. The larger each committee becomes, the greater will be its salesmanship ability in the community. These committees would be able to carry out the plans advocated by the state-wide committee.

Since publicity should be in the hands of the health department, it would be the duty of the state board of health to call the large state-wide committee into session and outline to them the definite plans which have been worked out by the medical association, through its committee for the control of syphilis, and the state board of health. The state committee can place in the hands of the sub-committees valuable information to be distributed in their communities. Through the agency of the state committee members (doctor and health officer) in the community, public meetings can be held with the sub-committees as a nucleus of attendance. Films, exhibits in the nature of poster displays, etc., can be obtained from the state board of health.

In *Journal of Indiana State Medical Assn.*, Hume Mansur Bldg., Indianapolis. Aug., 1937.

The Health Officer Reports—The Public Health Education Section meeting in the A.P.H.A. Annual Meeting are well and generously reported in *The Health Officer* (Nov., 1937), U. S. Public Health Service, Washington, D. C. The report of the opening session brings out the lack of agreement or of understanding as to what health education is or what it should accomplish.

Is it not possible to get a certain number of people to go to a clinic, to be immunized, to give up coffee, and to have a bowel movement every day—in short to adopt certain health practices—without educating? Some people can be belabored or frightened or "campaigns" into action—at least temporarily. Are they any more "educated" to this practice than the majority of automobile

drivers who refrain from parking in restricted areas because they know they'll get a ticket? Hence considering the objectives of health educational effort solely on the basis of the number of clinic attendances, number of diphtheria immunizations, or tuberculin tests seems inadequate. The panel brought forth no other basis for the evaluation of educational effort.

Also in this issue:

"Keeping Up With the Job" (a project in staff training in New York City Dept. of Health) . . . "Education Has 'Quacks' Too" (which should remind us to check up on any new source of information or help in health education).

Health Education in Nov., 1937, Journal—In *American Journal of Public Health*, Nov., 1937:

"Results of Mass Education for Tuberculosis Presentation in Detroit," by Vaughan, Harmon, and Molner (pp. 1116-1123).

"Education in Nutrition by Private Agencies," by Tobey (pp. 1124-1128).

"Results of Publicity" as to venereal diseases (p. 1128).

In "Prevention of Poliomyelitis" (p. 1164) mention of interest aroused by "recent widespread publicity."

Under "Sir Robert W. Philip—World Benefactor" (pp. 1168-1169) are the facts about "a semi-centennial of great social importance."

Under "A National Health Campaign" (p. 1172) is a brief mention of an English effort.

Under "Books and Reports" (p. 1182) see review of "The Traffic in Health."

Three health education items appear in "A Selected Public Health Bibliography" (pp. 1188-1189).

Under "Association News" (p. 1193) are listed 25 new members of Public Health Education Section; "Georgia Public Relations Bureau" (p. 1200); and a new director of health education under "Western States" (p. 1204).

Hygeia, December, 1937—Topics and titles in this issue:

Elixir of sulfanilamide deaths and new legislation (of timely importance) . . . "Chasing the cure" (a review of tb. facts) . . . Slimming scientifically . . . The truth about candy . . . Mates or mismates (what makes the difference) . . . Animals' aid to science (animal experimentation) . . . Paralysis at birth . . . Lighting the schoolroom . . . New books on health . . . Problem child or problem parents? . . . X-rays when cancer comes . . . Your mouth tells of general disease . . . Bad habits in good babies . . . Oliver Wendell Holmes (medical scholar) . . . Questions and answers.

In "School and Health":

Building the health curriculum in the high school . . . Field trips in health education (Camden, N. J., high school) . . . Some of our health needs (a teaching plan) . . . Energy foods for growth . . .

Under "Your Health" are 7 pages on the A.M.A. radio program, with material for school use. The topics are listed through the middle of June, 1938. Reprints of the school material are supplied at 5 cents, 25 for 50 cents. American Medical Assn., 535 N. Dearborn St., Chicago, Ill.

Letters and Good Will—Letters play a large part in both administration and education. In both they have to do with good will. Everybody is doing it—practically all staff members are writing letters. And letter writing is a technical job. It combines writing ability, with a fine sense of public relations. Few of the writers have had training, rules, or advice.

Leaders in business and industry have long been concerned over the quality of the everyday letters which help to create mental pictures of the firm and its business. Extensive campaigns of education and inspiration are conducted among writers of business letters. At last we have a pamphlet on creating good will for health and social work through the everyday letter

writing of the agencies. "Letters and Good Will," by Hilary Campbell, is for every health worker and office worker who writes letters. Social Work Publicity Council, 130 E. 22d St., New York, N. Y., will send a copy for 35 cents.

Again if we follow big business, some of us will discuss our letters in meetings of the professional and clerical staffs. A clinic session or a group of recent letters might be highly illuminating. Such chapter headings as "Style in Letter Writing" and "Opportunities to Win Friends" suggests discussion topics, in addition to such as these: "Over-worked words," "What to do about technical words." "What are technical or professional words to the layman?"

Health in Newspapers: Part 2—This month we reproduce a non-comic cartoon series, "What Do You Know About Health?" This is supplied to newspapers by Health News

FIRST CARTOON—Release September 13

What Do You Know About Health?

By FISHER BROWN and NAT FALK

Answers:
1. As a hygienist whose influence has made itself felt throughout the world, and as the first maker of sanitary laws, Moses may properly be regarded as the father of preventive medicine.
2. A contrivance that has worked its miracle of healing in countless cases where frozen feet might have led to gangrene. It has helped many suffering from arterial diseases. The glass boot stimulates cir-

ulation by means of gradual and rhythmic alternation of air pressure.
3. Decidedly. No child who gets his necessary quota of calcium, phosphorus and Vitamin D is plagued by rickets—a disease of the bones. Vitamin D is easily obtainable in cod-liver oil, Vitamin D milk and direct sunshine. Calcium and phosphorus have their richest source in milk. Vitamin D milk prevents rickets.

Service. 22 E. 40th St., New York, N. Y.

National Health Library—Located at 50 West 50th St., New York, N. Y., is a coöperative activity of the National Health Council. Is it as generally known as it should be?

It was established in 1922 by the consolidation of the libraries of four of the organizations included in the Council. It is supported by special contributions from member agencies and membership fees. While the collection is primarily for the use of the staffs of the supporting organizations and their members, it is open for reading and reference use, with certain restrictions, by any one interested in public health and allied subjects. The Library now contains about 6,000 volumes, 30,000 pamphlets and 500 periodicals including health bulletins and reports from states and principal cities.

The chief distinction of the National Health Library is its index of current periodical health literature, which is the most complete of any library in the United States. This is kept in the form of a card catalog.

Beside general public health and personal hygiene the main subjects covered are blindness prevention, child health, health education, mental hygiene, nursing, nutrition, personal health, public health nursing, psychoanalysis, sex education, tuberculosis, social hygiene and venereal disease prevention.

The Library does not have any pamphlets for free distribution or sale. It does have available or will compile bibliographies and reference lists on special subjects at a nominal cost.

Loan privileges are granted to those who are individual members of the following supporting organizations: American Public Health Association, American Social Hygiene Association, National Committee for Mental Hygiene, National Organization for Public Health Nursing, National Society for Prevention of Blindness, National Tuberculosis Association.

Others pay an annual fee of \$3. There is also an annual corporate membership of \$10 which permits, in addition to the privilege of borrowing books, special use of the Library, with certain restrictions.

Every Friday there is issued a four page mimeographed *Library Index* in which reference is made to the more important and interesting articles appearing in the current magazines received in the Library. Refer-

ences are included to city and state health bulletins not indexed in any other place. The subjects used are the same as those covered by the Library collection. The annual subscription is \$2.50 for those not on the staff of the supporting agencies.

The Library is open from 9 to 5 Monday to Friday; 9 to 1 Saturdays. Isabel L. Towner is Chief Librarian; Eva R. Hawkins, Associated Librarian.

MOTION PICTURES

The annual awards for the best amateur movies of the year include two by dentists, each presenting technical dental material. Such awards may suggest anew that there are possibilities in amateur films as teaching material for local as well as state staffs, and groups of coöperating agency staffs. The "best" pictures are described in *Movic Makers*, 420 Lexington Ave., New York, N. Y. Dec., 1937.

"1000 and One: The Blue Book of Non-Theatrical Films." The most extensive list of such films, on a wide range of subjects, with number of reels, content, nature of film, distributors, prices. Includes: embryology, anatomy, and structural physiology, eyes, feet, teeth, hair, child hygiene, food, personal hygiene, public hygiene, safety and accident prevention, fire prevention, nursing, first aid, life saving, disease and its treatment, medicine and surgery, parent education, psychology. *Educational Screen*, 64 E. Lake St., Chicago, Ill. 100 pages. 75 cents; 25 cents to subscribers to the magazine.

"Public Health in New York State" is the movie answer to those who ask what the State Department does. The picture runs about 20 minutes; is available in 16mm. and 35mm.

This is the first motion picture with sound produced entirely by the department through its Division of Public Health Education. It is developed around the district plan of health organization, with emphasis on the work of various divisions, as it is administered through the district health officers. Activities of 8 of the divisions are presented in detail, while work of the remaining 4 is covered in outline.

"What's in a Dress" is a new movie of the Woman's Bureau, Washington, D. C. It is a silent picture, and loaned, either narrow or standard width, to any interested organization willing to pay the nominal transportation charges both ways. In this review of problems in the clothing industry, sweat shop work in a tenement is pictured.

Among resolutions passed at the 1937 meeting of the Department of Visual Instruction, N.E.A., was the following:

WHEREAS, the Visual Instruction Department deplors the indiscriminate use of motion pictures in the school, therefore, be it

RESOLVED, that it urges greater attention be given by school toward securing and using only those motion pictures which are suited to the mental and maturity levels of pupils, and be it further

RESOLVED, that the department recommend that greater care be taken to distinguish more clearly between motion pictures used for specific classroom purposes and those more general motion pictures useful for auditorium or assembly activities.

The extent to which big business is making use of the motion picture is illustrated in a recent magazine advertisement. There were included pictures of the 212 sound projectors bought by one well known firm, the 110 projectors sold to another, the 104 to a third, and so on.

"Getting Started with Titles" is a brief, informal account of how one man undertook to make his own movie titles. Others may benefit by his experience. *Movie Makers*, 420 Lexington Ave., New York, N. Y. Dec., 1937. 25 cents.

In this department we have urged motion picture production as a health education project in schools. Now we have "The Movie Club as a Visual Education Project," by L. C. Spire. Tells how a club was organized to back the whole school curriculum; how the

costs are met by public exhibitions. In *Educational Screen*, 64 Lake St., Chicago, Ill. (Nov., 1937; 25 cents):

The equipment for producing 16mm. films is not elaborate or costly. Excellent cameras may be purchased for about the same price as a good snapshot camera. All of the other accessories including tripods, tilting stands, developing reels, and tanks, can be made. Our total outlay, exclusive of camera and projector, was less than \$5. This outlay enabled us to film pictures suited to our own particular needs which could not be procured elsewhere at any price. The possibilities are practically unlimited.

Is it within the scope of high school boys and girls? The films are of vital interest to them and they take pride in the making of their own movies. Has the club any value to the school and to the boys and girls of the club? The films are educational in nature and are produced to meet the particular needs of the classroom teacher. It would be difficult to over-estimate the value to the club members. . . .

SCHOOLS AND CHILDREN

"Alcohol and Narcotic Drugs," by Dr. Haven Emerson. *Journal, National Education Assn.*, 1201 16th St., N.W., Washington, D. C., Sept., 1937. 25 cents. "An urgent problem in health education"—and why.

"Evaluation of a Rural School Health Education Project," by Strang, Grout, and Wiehl. First of a series dealing with evaluation of the experimental school health education project in Cattaraugus County rural schools. *Quarterly*, Milbank Memorial Fund, 40 Wall St., New York, N. Y. Oct., 1937. 25 cents.

"Dental Health in Elementary Schools." Massachusetts Dept. of Public Health, Boston. Facts, teaching principles, teaching materials; table of contents and index. For teachers who need help most the reference lists could have been annotated to advantage. As is so frequently the case, although addresses are given for book and pamphlet publishers, periodicals are listed without addresses.

"Headed for Healthful Living," by M. B. Rappaport. *Journal of Health and Physical Education*, Ann Arbor, Mich. Nov., 1937. 35 cents. Outlines 8 essentials in a health teaching program; describes some applications in typical schools. Also: "A Sex Education Program," by H. C. Leibee. Reviews the need; states a wide range of community and school activities in education and prevention. In "Healthy Endings," H. T. Smith describes a "health game" or knowledge test which we should like to see in use among adults as well as children. A set of sentence beginnings parallel a set of endings, but not in the same order. Problem: which ending goes with which beginning. To use in classroom or elsewhere the two parts might be offered on written or mimeographed sheets. Or, the children might draw or cut out illustrations, mount them on cards, so that the two sets could be matched. Or, as an exhibit, the endings might be mounted on two revolving drums, mounted side by side, so that visitors could match them, a matched set to be supplied to every one who makes the try.

"Preparing Future Citizens to Support Public Health Measures," by Sally Lucas Jean. *Education*. May, 1937. Adequate school health examinations, and effective teaching of personal and public health needed if future citizens are to value properly public health services. Reprint from the author: 200 Fifth Ave., New York, N. Y.

In *Public Health Nursing*, 50 W. 50th St., New York, N. Y. (35 cents):

Sept., 1937: "Building for Health in a Secondary School" . . . "Health Explorations of Eighth Grade Children" . . . "The Nurse's Contribution to Health Education" . . . "New Ways for Old in Rural School Health" . . . "Present Trends in Health Education."

Oct., 1937: "Approaches to Sex Education in the Schools" . . . "Who Is Prepared to Teach Health?"

Nov., 1937: "Habit Training During the Preschool Years."

REPORTING

As usual the opening feature of the East Orange, N. J., Board of Health report is a diagram based on the *Appraisal Form*. Here we have the total score of 932, and the details in black and white bars for vital statistics, infant hygiene, etc. Popular health instruction is missing, but gets two pages of text, and a photograph of the Information Room, "to which the public first comes as it enters the building" and which "continues to serve a useful part in education."

The annual report of Visiting Nurse Assn., 205 W. Main St., New Britain, Conn., is printed on one sheet which is folded so that it makes 12 pages, 3½ by 9 inches, with a 3 page spread of pictures entitled "Serving New Britain in Sickness and Health." One page is used for the mailing addresses.

Health, Lansing, Mich., for Oct., 1937, is an extensive, profusely illustrated number commemorating the 30th anniversary of the Michigan Tuberculosis Association.

"The Health of Madura City," reports activities of the Health Department of that far southern India community. The health education record includes cinema shows (510), magic lantern demonstrations (288), lectures and talks (3,847), each about doubling over the preceding year.

The mimeographed report of the Los Angeles, Calif., County Health Dept. explains that the Bureau of Maternal and Child Hygiene "is largely an educational activity in instructing mothers in the proper care of their children, as well as many other types of maternal and child health problems. For this reason a great deal of work is done with schools, women's clubs, and organizations of a similar type."

"A New Day Dawns for Birth Control" is the "concluding report" of the National Committee on Federal Legislation for Birth Control, 17 W. 16th St., New York, N. Y. This "summary of 7 years which led to legalization and cleared the way for an epoch-making advance" is largely a record of education, propaganda, and of legislative effort—which is largely educational.

Possibly the simplest form of annual report to be mailed without an envelope is that of the Public Health Nursing Assn., 519 Smithfield St., Pittsburgh, Pa. Concise report paragraphs are headed: "Highlights," "We Point With Pride," "We View With Alarm," "We Look Ahead."

A two year report makes up the Oct., 1937, issue of *Bulletin*, American Society for the Control of Cancer, 1250 6th Ave., New York, N. Y. There are paragraphs on exhibits, talking film slides, and film strips issued by the society.

The 1936 report of the Newton, Mass., Health Dept., contains a two page table of contents, with all sub-headings under the main chapter headings. This seems more useful in a small city report, than the index which is so needed in the reports of larger cities and states. Health education includes professional, nursing, and general. Under the last is brought out the limitations experienced in the smaller city overshadowed by a big neighbor. The last chapter is made up of brief reports of health work by local voluntary agencies.

"Report for the First Half of 1937 on the Project of Arousing and Developing Citizen Interest in and Support of Work for the Control of Syphilis in New York State, outside of New York City." An 11 page mimeographed report of the State Committee on Tuberculosis and Public Health,

S.C.A.A., 105 E. 22d St., New York, N. Y. This report may serve as a useful check list illustrating the range of activities and educational materials to be drawn upon by other health agencies.

"Statement of Membership and Activities, 1937-1938," National Health Council, 50 W. 50th St., New York, N. Y. Reporting the N.H.C., with a page or two on each of the member agencies, national health associations, their nature, services, etc.

When "contents" may fail to grasp its opportunity for usefulness is illustrated by a department of hospital report. The "contents" reads:

Introduction, page 6; Divisions, page 7; Institutions, page 43; Capital Outlay Budget, page 78; Coöperating Groups and Agencies, page 82; Department Progress, page 89.

There are 28 divisions, and 29 institutions to be located by the above "contents," without an index.

DATES AHEAD

Sometimes you get health agencies represented on committees for celebrations conducted by other groups. Sometimes a press release, an interview, the caption to a photograph, will make a health tie-up. Or you may send a letter of suggestion which carries over your idea. Again, a little celebration by your own staff may serve the purpose.

International Leica Exhibit, Jan. 8-15, 1938, International Bldg., Rockefeller Center, New York, N. Y.

Jan. 17 and 18, 1938, Conference on Better Care for Mothers and Babies. U. S. Children's Bureau, Washington, D. C.

Jan. 22 is anniversary of organization of first free school dental clinic in America. Consult Children's Aid Society, New York, N. Y.

Child Labor Day, Jan. 29, 30, or 31, 1938. Write National Child Labor Committee, 419 4th Ave., New York, N. W. Send 25 cents for packet of child labor literature.

Feb. 2, 1938, will be the second *National Social Hygiene Day*. Address: American Social Hygiene Assn., 50 W. 50th St., New York, N. Y.

Candlemas or "Ground-Hog Day," Feb. 2. Whether it does, or does not!

Feb. 10, anniversary of *opening of first modern hospital*. See "News Almanac for Social Work" (Community Chests and Councils, 155 E. 44th St., New York, N. Y.). Consult American Hospital Assn., 18 E. Division St., Chicago, Ill.

Feb. 13, 1938, *Race Relations Sunday*, introducing *Interracial Week*. Address: Dept. of Race Relations, Federal Council of Churches, 297 4th Ave., New York, N. Y.

St. Valentine's Day, Feb. 14, may be given a health slant.

May 15, 1938: Closing date for Competition in Small Sculptures in White Soap. Address: National Soap Sculpture Committee, 80 E. 11th St., New York, N. Y. For students, sanatoria patients, and others.

FOR REFERENCE OR EDUCATION

Of course the notes which appear from time to time under this heading should be classified, and more fully annotated. Satisfactory classification for all the audiences among our readers is not possible here. What could be educational in one group would be quite out of place with another.

We here seek to do little more than to make the wide range of material accessible to planners, writers, executives, teachers, and others, who in turn may be expected to select and to describe what will best serve the needs of their respective groups.

Again we would suggest that a single copy, or a half dozen copies, of a selected publication may be used to splendid advantage toward interesting an influential individual, or in helping the leader of a group.

"The A-B-C of Syphilis." New Jersey State Dept. of Health, Trenton. 7 pp. "What the average person should know about a very dangerous and prevalent disease" appears on cover page. Examples:

Accidents are often the direct result of Syphilis.

Advertised drugs for self-treatment of Syphilis are dangerous. Avoid them.

Adequate medical treatments are the only way to cure Syphilis.

Alcohol and Syphilis are close companions.

Again C. LeRoy Baldridge, so well known for his posters and book illustrations, has painted a poster for the N.O.P.H.N. A public health nurse at the door of a home being welcomed by the children—beautifully executed in four colors on fine quality heavy stock. There is space in which to localize poster. 50 cents; 12 or more, 25 cents. N.O.P.H.N., 50 W. 50th St., New York, N. Y.

"Citizen Support in Syphilis Control," by Homer Folks. *Venereal Disease Information*, Supt. of Documents, Washington, D. C. Oct., 1937. 5 cents. How individuals and groups cooperate to advantage.

A clever use of humor to point a health moral is to be found in a reprint, "Thank God for Lip-Rouge," from *Health Officers News Digest*, 30 Rockefeller Plaza, New York, N. Y. Free. An effective adaptation has been made in the form of a display card 11 by 14 inches.

"Equipment for a Nursing School Library," by S. T. Smith. *Am. Journal of Nursing*. Aug., 1937. May be useful outside of the nursing school field.

"Experimental Syphilitic Keratitis in the Rabbit," by Dr. A. J. Gelarie, 52 W. 74th St., New York, N. Y. Reprint.

From "abscess" to "yellow fever," from the communicable diseases of childhood to the trend of longevity, a wealth of statistical reference data is contained in "Twenty-Five Years of

Health Progress," by Louis I. Dublin and Alfred J. Lotka. Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

"Low Cost Food for Health." An attractive looking pamphlet of 75 pages with food, meal, marketing, and cooking information; two-thirds devoted to recipes; a detailed table of contents for the recipes in the back (even though it happens to be labelled "Index"). Community Health Assn., 137 Newbury St., Boston, Mass. 25 cents?

"Maternal Care," by Dr. F. L. Adair, University of Chicago Press, Chicago, Ill., for American Committee on Maternal Welfare. Basic principles for the professional.

"Milk Control: Governmental Regulation of the Dairy Industry in the U. S." Public Administration Service, 850 E. 58th St., Chicago, Ill. 75 cents. What federal, state, and local agencies are doing; regulations; laws, surveys, etc.; special chapter on publicity and educational work.

"Need for More Nutrition Education." Dairy Council Digests, National Dairy Council, Chicago, Ill. Free.

"Practices and Experiences of the Lavanburg Homes." Lavanburg Foundation, 132 Goerck St., New York, N. Y. A housing experiment for the real "slum" dwellers.

"Public Health Work Helps Private Practitioners," by F. M. Houser, M.D. *Health Bulletin*. State Board of Health, Raleigh, N. C. Dec., 1937. A good case is made for public health departments.

"Transiency: A Public Health Menace." Tuberculosis Abstracts, National Tuberculosis Assn., 50 W. 50th St., New York, N. Y. Oct., 1937.

A triple letter-sheet spread of well arranged newspaper clippings. Henry Street Visiting Nurse Service, 99 Park Ave., New York, N. Y.

"Vitamin Content of Foods," by Daniel and Munsell. Supt. of Docu-

ments, Washington, D. C. 15 cents. Professional study.

"The Wonderful Story of Life." U. S. Public Health Service. A parent's talks with children regarding life and its reproduction. Supt. of Documents, Washington, D. C. 18 pages. 10 cents.

List of publications. Social Work Publicity Council, 130 E. 22d St., New York, N. Y. Dec., 1937. Free.

American Medical Assn., 535 N. Dearborn St., Chicago, Ill.;

"Gonorrhea," by Warner and Warner, and "The Gonococci," by H. L. Herschensohn. 15 cents. . . . "Syphilis," by Warner, "Spirochaeta Pallida," by Herschensohn, and "The Wassermann Test," by Kolmer. 15 cents.

American Social Hygiene Assn., 50 W. 50th St., New York, N. Y.:

"Prostitution in the U. S.," by Bascom Johnson. 10 cents. 18 pp. . . . "A Current View of Prostitution and Sex Delinquency," by Bascom Johnson. 10 cents. 14 pp. . . . "What You Should Know About Syphilis and Gonorrhea," by M. J. Exner. 72 pp. 15 cents. . . . "The Newest Generation," by William F. Snow. 10 cents. 9 pp. . . . "The Drama of Syphilis," by C.-E. A. Winslow. 10 cents. 16 pp. . . . "Social Hygiene and the Public Mind," by David Resnick. 10 pp. 10 cents. Reviews progress against syphilis discussion taboo.

Children's Bureau, Washington, D. C.:

"Home Play and Play Equipment" . . . A group of separate charts and tables on maternal mortality for statements comparing cities and states, etc. . . . "A General Plan and Objectives of a Maternal and Child Health Program" (reprint) . . . "Suggested Methods of Improving the Health of the American People" (reprint) . . . Development of a Leisure-Time Program in Small Cities and Towns." . . . "Esta Vd. Educando a Su Nino a Ser Feliz?"

National Tuberculosis Assn., 50 W. 50th St., New York, N. Y.:

"The Tuberculin Test" (4 p. folder).
"The Double-Barred Cross: Symbol of the World-Wide Campaign Against Tuberculosis" (3 p. folder; significance, history, and use).

Reprints (10 cents each) from *Public Health Nursing*, 50 W. 50th St., New York, N. Y.:

"Community Partners" (chests and v.n. assns.) . . . "Study Outline: Lay Participation in Public Health Nursing" . . . "Building for Health in a Secondary School" . . . "New Ways for Old In Rural School Health" . . . "A Program for Staff Education: Pneumonia."

CONVENTIONS: PAST AND FUTURE

At the *sixty-third annual meeting* of New Jersey Health and Sanitary Assn.: A continuous program of 12 motion pictures . . . microscopic exhibits by Bureaus of Venereal Disease Control and Bacteriology of State Dept. of Health . . . "Health Education in Its Broader Aspects," by Dr. Livingston Farrand. From *Health Progress*, Freehold, N. J. Nov., 1937.

On the program of the annual Illinois State Conference on Public Health: "Community Education in Communicable Disease Nursing."

Why not do something about the next state meeting of social workers, or any state or national meeting of health workers? Why not have a health education and publicity session? Breakfast, luncheon, or informal dinner?

If you have no other idea for a program offer "Question and Answers." Invite questions in advance. Have your questions written out ready to start the meeting. The audience will quickly supply more questions. The chairman can answer some questions and get the audience to help. A committee of two or three could help the chairman handle the questions.

Merely opinion questions could be answered by raising hands. How many believe so and so? How many believe something else?

MAGAZINE ARTICLES

"Condition Satisfactory," by Dr. Sandor Pudor. A Viennese physician has written of his own physical and psychological reactions to three operations. "Sight Without Glasses," by Dr. H. W. Peppard. The use of exercises. "Man, Bread and Destiny," by Furnas and Furnas. What man does to food; what food is doing to man. Condensed in *Book Digest*, 350 E. 22d St., Chicago, Ill. Dec., 1937. 25 cents.

"The Heritage of Ignorance," by G. Zilboorg. *Atlantic Monthly*, Boston, Mass. June, 1937. 40 cents. Includes psychiatry. Quotes Artemus Ward on ignorance as not lack of knowledge, but as "knowing so many things that ain't so."

"Hope for Crippled Children," by Dr. W. R. Ramsey. *Farmers Wife Magazine*, St. Paul, Minn. Dec., 1937. A copy free to a health worker.

Life, in its Nov. 29, 1937, issue gave 8 pages to tuberculosis and the Christmas Seal. The publishers sent a copy to each state tuberculosis association and tuberculosis sanatorium.

Six picture pages about tuberculosis (including a half page picture from that time when tuberculosis patients "drank the blood of freshly slaughtered cattle to give them strength"); and 2 pages of open-air treatment in Europe; 3 pages of fire and water life saving; 16 facts about bathing a baby. *Look*, Des Moines, Iowa. Dec. 7, 1937. 10 cents.

"Syphilis." Two book reviews by Ira V. Hiscock. *New Republic*, New York, N. Y. Oct. 6, 1937. 15 cents.

Reviews of the current books on syphilis have added immensely to the magazine and newspaper space given to the subject.

BOOKS AND REPORTS

Clinical Parasitology—By *Charles Franklin Craig, M.D., Colonel U. S. Army (Retired), and Ernest Carroll Faust, Ph.D.* Philadelphia: Lea & Febiger, 1937. 733 pp. Price, \$6.50.

This new textbook by leading American authorities on tropical medicine and parasitology from the Tulane University School of Medicine is intended for practising physicians, medical students, and other students of these subjects. It is a well balanced volume covering the fields of protozoölogy, helminthology and entomology as they apply to the animal parasites of man and their vectors. It is divided into three sections, one for each of the above divisions of the field, and is supplemented by an appendix describing the technic of collection, preparation and identification of the parasites, and giving a list of representative specimens desirable for teaching and the *International Code of Zoölogical Nomenclature*. Finally, there is an extensive reference list of textbooks, journals, and references to the subject and a complete index.

Colonel Craig has prepared the section on protozoa and Dr. Faust the sections on helminths and arthropods. Each section is introduced by a general consideration of the morphology, biology, and classification of the parasites concerned, and each sub-group of parasites is introduced by a zoölogical classification. The individual parasites are treated from the historical, geographical, and morphological points of view; their habitats, life histories, and epidemiology are described; their pathological effects on the host and the clinical symptoms produced are presented; and methods of diagnosis described, followed by a consideration

of treatment and prevention. The many previous first-hand studies and publications of these authors in their respective fields and their activities in teaching and research work up to the present time have insured a completeness of authoritative and correct presentation of facts which could hardly be exceeded at the present time. Colonel Craig has especially drawn upon his expert knowledge of amebiasis and malaria, using much of the material on amebiasis which appeared in his recent volume *Amebiasis and Amebic Dysentery*, and Dr. Faust has reproduced and brought up to date much of the subject matter in his volume *Human Helminthology*.

The value of the book is enhanced by a judicious use of tables and by 243 engravings, both original drawings and photographs, and many others borrowed from other publications. The book is remarkably free from statements of doubtful facts, argumentative points, and typographical or editorial errors.

The reviewer is in agreement with nearly all of the points of view expressed as far as his familiarity with the subject is concerned. In the consideration of the pathology of visceral Leishmania infection more emphasis might have been placed upon the almost exclusive participation of the reticulo-endothelial cells throughout the body and the paralyzing effect of the infection on the bone marrow, producing a reduction in platelets and a prolonged bleeding time as well as a secondary anemia and leukopenia. In the treatment of Leishmania infections the modern use of pentavalent antimony preparations replacing the use of tartar emetic might have received

greater emphasis. In the treatment of hookworm, carbontetrachloride is listed among the drugs advocated without emphasizing its occasional fatal toxicity and without warning against the use of fats and alcohol in the diet close to the time of administration. Preliminary purging is advocated in connection with all anthelmintics although it is generally conceded that this is unnecessary with some anthelmintics and is often harmful with carbontetrachloride. In connection with the bite of the black widow spider the statement is made that the site of the bite becomes red and swollen, whereas in the reviewer's experience there is usually no local inflammation whatsoever. The rise in blood pressure associated with this condition, which is of diagnostic importance, is not mentioned.

The book is beautifully printed and bound and both the authors and the publishers are to be congratulated on its accomplishment. It will undoubtedly become a standard textbook in its field.

HENRY E. MELENEY

Feeding Behavior of Infants—By *Arnold Gesell and Frances L. Ilg*. Philadelphia: Lippincott Co., 1937. 201 pp. Price, \$4.50.

With characteristic thoroughness and scientific precision, Gesell and Ilg have produced a book which should be of absorbing interest to physicians, nurses, and educators. Strictly speaking, it is not a book on infant feeding. Feeding is simply one of the behavior reactions in the growth of the total personality of the child. The authors succinctly describe the volume as "A Pediatric Approach to the Mental Hygiene of Early Life."

The book incorporates the results of an enormous amount of research carried out through the Yale Clinic of Child Development in coöperation with the Visiting Nurse Association and the

Well Baby Conferences of New Haven. The same use of pictorial illustrations is made as was used so extensively in Gesell's *Atlas of Infant Behavior*. One hundred and thirty-two well selected, unique photographs are included in the present volume.

Part I treats of the behavior aspects of nutrition, Part II of the growth of feeding behavior, and Part III of the regulation of feeding behavior. An appendix rounds out the volume with interesting and instructive illustrative biographies of actual feeding cases. A selected bibliography of the important contributions in this field increases its usefulness. The book is well arranged for reference and is beautifully printed.

RICHARD A. BOLT

Anatomy and Physiology of Physical Training—By *Major R. W. Galloway*. Baltimore: Wood, 1937. 182 pp. Price, \$2.50.

This brief, condensed treatise attempts to cover in Part I the principles of anatomy and physiology as related to physical training. Part II presents the practical application of these principles to training.

Among others, it has a chapter on breathing exercises and one on corrective exercise. Its major objective is in the field of body mechanics. It seems too sketchy to give real grounding and application.

CHARLES H. KEENE

Some Fundamental Aspects of the Cancer Problem—Edited by *Henry B. Ward*. New York: Science Press, 1937. 248 pp. Price, \$2.50.

The general interest in cancer has led to the publication of this supplement to Volume 85 of *Science* containing 31 papers or abstracts of papers read at the Atlantic City meeting in December, 1936. The first group concerns heredity and constitutional fac-

tors. Maud Slye summarizes her work with the statement that malignant disease is transmitted through the genes as a recessive character and that carcinoma, sarcoma and leukemia have different general and localizing characters. She believes that there is no evidence of the operation of an extra-chromosomal factor.

On the other hand, C. C. Little believes the evidence shows that the most important influence in determining the incidence of breast cancer, although it has a genetic basis, is evidently affected by factors of the internal environment and that evidence is steadily accumulating to support the hypothesis advanced by Tyzzer in 1915 that the cancer cell differs from the normal by a process of mutation.

Clara Lynch believes that the results of her studies on spontaneous lung tumors in mice shows that heredity plays some part in controlling the appearance of tumors in this organ.

On the other hand, the very extensive work of Bullock, Curtis, and Dunning, studying tumors produced by known agents such as cysticercus larvae, a parasite which develops in the liver, and also some of the carcinogenic hydrocarbons, points to the fact that the possibilities of cancer development must be a universal cell characteristic and that the histogenesis of the tumors is determined by the fortuitous exposure to an irritant of the various types of cells which characterize neoplasms in general.

F. C. McDowell concludes that the incidence of leukemia is determined by intrinsic and extrinsic factors, but he also shows that even in a genetically uniform strain of leukemic mice not all develop the disease.

The second group of papers discusses the artificial production of tumors and is prefaced by a paper on the synthesis of a large number of fairly simple

hydrocarbons contained in the phenanthracene group.

F. C. Wood discusses the great variety of tumors which have been produced in animals and calls attention to the fact that it has not been possible as yet to produce neoplasms in cells growing in culture though exposed to a potent carcinogenic agent.

R. S. Ferguson calls attention to the fact that the malignant tumors of the testes are neoplastic growths of the germ cells and hence give rise to tumors of a teratoid nature.

H. J. Bagg follows with a demonstration of the production of a teratoma in the testicle of the fowl by the injection of a zinc chloride.

J. B. Murphy reports on his studies of the stimulating and inhibiting agents obtained by the use of various cell extracts.

Finally, the volume contains a series of studies on the production of high voltage radiation, the determination of X-ray qualities by filters, comparative effects of neutrons and X-rays on tissues, biological effects of alpha particles, and ends with some excellent statistical and general papers. The whole offers a good cross-section of cancer research at the present time.

FRANCIS CARTER WOOD

Malaria in Europe—By L. W. Hackett. New York: Oxford University Press, 1937. 336 pp. Price, \$3.75.

Dr. Hackett's book is a valuable contribution to the book-shelf of the malariologist, the physician, the public health worker, and the layman interested in controlling the disease. The style is delightfully easy and the illustrations are well chosen.

Although Dr. Hackett has thoroughly documented his narrative and demonstrated his points by citing other experiences as well as his, yet he presents his theories and conclusions as entirely

his own. This lends much to the clarity and value of the book.

In discussing the epidemiology of malaria, showing its dependence upon the relation of the habits of the insect carrier to the habits of man, Dr. Hackett discloses the distinctive habits of the newly discovered races of *A. maculipennis*. In describing the ebb and flow of the disease in Europe through the centuries, he recounts briefly the controversies over anophelism without malaria and over zoöphilic barriers as controls. He shows how the recently acquired knowledge of the distribution of each race of *maculipennis* ends these controversies.

The complexity of the malaria parasite and the rôle of immunity are delightfully treated. His discussion of the variation of strains within each species of plasmodium clears up many misconceptions by giving accurate descriptions of parasite reactions to given treatments. We welcome such a brief resumé of a voluminous literature.

All physicians in the South and all malariologists should read the chapter on "Treatment in Theory and Practice." Those interested in attempts to control malaria infection rates by means of any anti-malaria drug should carefully study it. Here is given a well digested view of the rôle, dosage, and duration of treatment of each of the anti-malarials and their respective efficacy for each species of plasmodium as well as a clear discussion of cases which depart from the rule. He differentiates between temperate climate malaria (with a winter season of no transmission) and the same disease with its different manifestations under tropical conditions. He explains clearly how to appraise a malarial situation and summarizes the determining factors in selecting a method of control for any malaria project.

Dr. Hackett discusses what results may be expected from drainage,

larvicide application, or screening, without distracting the reader's attention by lengthy descriptions of the minutiae of each method of anopheline control.

The book concludes with two thoughtful illustrations of unusual though logical methods of meeting two different malaria situations—solutions arrived at from a careful study of epidemiological data rather than the haphazard application of any standard control measure.

LOUIS L. WILLIAMS

Childbirth Yesterday and Today
—By A. J. Rongy, M.D. New York: Emerson, 1937. 192 pp. Price, \$2.00.

Safely Through Childbirth—By A. J. Rongy, M.D. New York: Emerson, 1937. 192 pp. Price, \$2.00.

These companion volumes give a concise description and a clear picture of the progress of midwifery and obstetric practices throughout the centuries. They elucidate step by step the application of scientific methods to the solution of difficulties encountered in childbirth.

The historical narrative is presented delightfully and is illustrated with telling pictures. A sketch of the history of child care with reference to the father as well as the mother makes interesting and instructive reading. Brief, well balanced chapters on birth control and childbirth today are included.

Safely Through Childbirth is a practical small volume on prenatal, natal, and neonatal physiology and hygiene. It describes in non-technical language the changes involved in the organism in motherhood, stressing the importance of prenatal and postnatal care. A timely chapter on abortion is included.

The convenient size and composition of these two volumes should assure them a place in the educational efforts

now being made for the prevention of maternal mortality and morbidity.

RICHARD A. BOLT

Textbook of Psychiatry—By Arthur P. Noyes, M.D. (2nd ed.) New York: Macmillan, 1936. 329 pp. Price, \$2.50.

This book does unique justice to the field of psychiatric nursing and, indeed, in synoptic form, to the broad field of general psychiatry. This second edition represents a thorough revision of the previous text. Not only does this book pay respect to increasing knowledge which has been rapidly enhancing psychiatric usefulness, but also gives a commendable psychiatric attitude and insight which may be termed "constructive psychiatric intelligence."

Of particular note is the attention paid to the common maladjustments of life, the significance of behavior and personality manifestations observed in the wards and clinics of general hospitals as well as those in connection with mental hospitals. The author's conception of mental health as a real and individualistic matter, together with emphasis upon the integration concept, is indeed noteworthy.

The nurse's own rôle is understanding her personality development not only from the standpoint of self improvement or social adjustment and individual efficiency but also because of her influence upon the lives of those she serves, receives critical amplification in the final chapter, *The Nurse and Her Profession*.

The explicit style of the writer makes the reading of this text both interesting and easy to grasp. The genetic-dynamic approach to each of the subjects discussed is in keeping with present-day psychiatric knowledge and practice. The author is wholesomely eclectic in his attitude toward the various schools of psychiatry but seeks to bring to the surface the core of their respective

contributions in the light of possible usefulness to the nurse.

A well chosen glossary and index conclude the book. The references for further reading at the end of each chapter have been critically chosen although certain typographical errors in respect to names no doubt will be corrected in succeeding revisions.

FREDERICK L. PATRY

Junior Clothing—By Kate W. Kinyon and L. Thomas Hopkins (rev. ed.). New York: Sanborn, 1937. 262 pp. Price, \$1.16.

Once there was a book *Junior Foods and Clothing*. Now each subject has been elaborated into a separate book. *Junior Clothing* is a 9 chapter textbook for use in junior high school home economics classes. The subjects developed are use, appearance, design, color, textiles, under-garments, selection, repair, and how to fit the clothing problem into the family scale.

Within the clothing situation as it now exists, these titles are developed in great detail even unto "rhythm in arranging lines and spaces." The text, however, makes no attempt to correct existing foolish practices, as for example, why men should slavishly continue to wear neck-choking shirts and ties, heat-retaining vests and coats, and monkey jackets. Most of the book, unfortunately, is for that sex which is already too far ahead of the other in matters of health, comfort, variety, and particularly appearance of clothing. The authors missed an opportunity to help the mere males. W. W. PETER

Junior Foods—By Kate W. Kinyon and L. Thomas Hopkins (rev. ed.). New York: Sanborn, 1937. 362 pp. Price, \$1.16.

This is a companion book to *Junior Clothing*, and is likewise designed for general use as textbook in junior high school home economics. The 8 units

cover necessary foods, breakfast, lunch, dinner-choices, the why of preserving foods, food purchasing, cooking utensils, recipes in food preparation.

The authors have stood commendably adamant against yielding to the ballyhoo of Hollywood diets, food faddists, and some of the more insidious council-approved commercialized food advertising. An example is the subject of vitamins so vitally invigorating to all of us, especially to various manufacturers. It is strenuous enough for even the professionally trained to keep up with the vitamin procession. The authors have fortunately avoided confusing children's minds with too much technical material. They mention the alphabetical list of vitamins, tell what regulatory stunts they perform in the body, list the variety of overlapping foodstuffs harboring these elemental substances, and let it go at that before all interest on the part of the child is lost. In like manner the essential salts are reviewed.

The illustrations are particularly interesting because the subject of food use lends itself to startling photographic contrasts—big and little rats, pigs, dogs, and children, all snapped just as they stand to show the difference between right and wrong feeding.

There is so much good material in this book that one can forgive the continued use of doubtful material such as the 4 pages of height-weight-age tables for boys and girls lifted from ancient traditional sources and printed without reference to variations due to racial stock and physical build.

W. W. PETER

Principles and Practice of Public Health Dentistry—By J. A. Salzmann, D.D.S. Boston: Stratford, 1937. 584 pp. Price, \$4.00.

As far as our reading goes, this book in its entirety covers a new field, or perhaps it is more correct to say that

the author has gathered and put under one cover subjects which until this time it has been necessary to search for through quite extensive literature.

"Dental public health is presented from an evolutionary standpoint in Part I; from the professional viewpoint in Part II; from the viewpoint of Public Health in Part III; while Part IV constitutes a handbook on dental public health practice." It would be hard to say which of these is the most interesting. It is perhaps safe to say that the first part covers ground which is less generally known to the medical profession, at least, than the others. Parts II, III, and IV are eminently practical, but also contain a great deal of history, especially Parts II and III.

From the standpoint of the readers of this *Journal*, probably Part III, which deals with the public health aspects of dentistry, is the most important, but all hang together to make an excellent whole. Part IV gives the program for dental public health, which is well thought out and practical. It contains chapters by Dr. Harry Strusser, Chief of the Dental Division, Bureau of School Hygiene of the Department of Health, New York City; and by Dr. John Oppie McCall, Director of the Murry and Leonie Guggenheim Dental Clinic.

We consider this book one of unusual value, which we hope will be read by health officers and public health workers generally. It is a strong plea for the recognition of oral hygiene and dentistry in our programs of public health. The author emphasizes, very properly in our opinion, the discoveries of dentists and the part they have played in proving the relationship of the condition of the mouth and teeth to the general health. It is true that in some ways they have in the past gone too far, but a better understanding of their attitude and facts on the part of the medical profession might have

saved us from the orgy of tooth pulling for the cure of every ailment to which flesh is heir—now happily a thing of the past.

The book is well and interestingly written. The author does not hesitate to show up some of the failures of the profession in the past, but, as already pointed out, also tells us of its triumphs and sacrifices, which mark it as a decidedly human document.

The illustrations are excellent and the book is well documented, with a bibliography at the end of each section. A good index adds to the value of the book. We wish for it a wide circulation among all public health workers and health officers, and also in the medical profession.

MAZÏCK P. RAVENEL

Research Memorandum on Social Aspects of Health in the Depression
By Selwyn D. Collins and Clark Tibbits. New York: Social Science Research Council, 1937. 192 pp. Price, \$1.00.

Research Memorandum on Crime During the Depression—By Thorsten Sellin. New York: Social Science Research Council, 1937. 133 pp. Price, \$1.00.

These two volumes are part of a series of 13 monographs on the social aspects of the depression published by the Social Science Research Council under the direction of its Committee on Studies in Social Aspects of the Depression. The purpose of these is not so much to gain new information as to survey existing data, discover unfilled gaps in information, and suggest practicable research problems.

The problem set by Collins and Tibbits is to explore the fields of health measurement, measure changes in the health environment, and assess changes in organization and methods of preventing and treating illness. Recognizing the difficulties in establishing

standards of physical fitness in terms by which the health status of populations may be measured, the authors suggest that changes in health may best be determined indirectly through variations in mortality rates, sickness rates, and prevalence of physical defects including malnutrition and underweight. The principal indexes of health measurement suggested are: (1) infant neonatal and maternal mortality and stillbirths; (2) general mortality rates; (3) morbidity or sickness rates; (4) accidents; (5) nutrition, height and weight. The principal sources of data relative to the above indexes are indicated and methods of using them to evaluate changes in public health during the depression are suggested.

The second part of the study is concerned with changes which may have taken place in the public health as a result of alterations in the economic status of large groups in the population. The writers point out that changes in income and economic status are significant only in so far as they affect the fundamental factors necessary to health, such as food, shelter, clothing, and other conditions necessary to health maintenance. Since such changes probably take place as the proportion of the population living at or below subsistence levels changes, research is suggested along 4 lines: (1) minimum subsistence incomes; (2) consumption levels; (3) occupational environment or working conditions; (4) changes in the social environment. The third line of investigation suggested is a study of recent changes in community technics for providing facilities for the prevention and treatment of illness.

The emphasis in this as well as other volumes in the series is placed on research. The authors have done an excellent job in making available the results of a great many important investigations, locating the primary sources of data and suggesting research

problems which seem likely to throw light on what has happened to the public health during the depression. Researchers will find the study an invaluable guide. Its greatest value lies in orienting the student in the field and showing him the directions in which future research seems to hold the greatest promise.

In the second memorandum Professor Sellin outlines a research program for the study of the possible effects of the depression on crime trends. Since the law defines the nature of crime, the author believes that any study of trends must begin with an examination of the changes in the law itself. We need to know what conduct, previously legal, is now criminal, as well as what illegal conduct has been dropped from the law. We need to know what changes have taken place in the severity of penalties imposed by the law before we can estimate the changes which may have occurred in the amount of crime during the depression. In chapters two and three, studies of the relation between economic fluctuations and crime, in Europe as well as in the United States, are reviewed. The results of these studies, most of them made before the depression, are rather disappointing. They indicate the almost insuperable difficulties of attempting statistical measurements of such complex relationships as may exist between crime and economic change. Some of the basic difficulties in such statistical correlations are set forth in the next chapter on the "index question." The final problem suggested is an analysis of administrative agencies; the police, the courts, and the penal and correctional institutions and agencies. In the last chapter Professor Sellin suggests some next necessary steps in research to test the validity of a series of common theories concerning the effects of economic fluctuations on crime. The value of this memorandum lies in show-

ing how little we know scientifically concerning matters about which opinions are so commonly and so dogmatically held. C. T. PIHLBLAD

Federal and State Control of Milk Prices—By James A. Tobey, Dr.P.H. Chicago: International Association of Milk Dealers, 1937 42 pp. Price, \$2.00.

This concise volume supplements effectively *The Legal Aspects of Milk Control* by the same author. Members of the dairy industry as well as milk control officers will find useful this discussion of government regulation of milk prices and the production and distribution of milk. The volume reviews the Constitutional status of laws fixing prices and regulating the production and distribution of milk as shown by court decisions. IRA V. HISCOCK

An Introduction to the Social Studies—By Joseph K. Hart, Ph.D. New York: Macmillan, 1937. 203 pp. Price, \$2.00.

While this book is not concerned primarily with the public health, it is a book that every public health worker should read. The author modestly calls it an elementary text book for professional and preparatory groups. While this may define its roots, the ramifications of its branches cover most of the problems of a modern democratic order and give us an excellent picture of contemporary social problems.

The chapters on "A Healthy Social Order," and "Our Social Profession," should prove especially helpful to those who are trying to clarify their social vision. The book is written in an easy style and its chapter divisions are arranged to carry the reader along from one interest to another. Each chapter is followed with suggestions for further study, and a selected book list appears at the end of the volume.

RICHARD A. BOLT

Russian Medicine (Clio Medica)
—By E. Horsley Gantt. New York:
Hoeber, 1937. 214 pp. Price, \$2.50.

The little volume is more than a history of Russian medicine. It is also a thumb-nail sketch of the history of Russia as well. The reviewer read this book with great interest. It contains a great deal of solid information regarding Russia and recounts enough dramatic incidents to save it from being too heavy.

All references to Russian medicine inevitably contain a eulogy of Pavlov just as similar books on medicine in Spain emphasize the importance of Ramon y Cajal. This is, of course, as it should be, but it also emphasizes the sterility of medicine in these two countries.

The last chapter in the book on

Soviet Medicine should be of particular interest to many American physicians who fear that attempts are being made to Sovietize American medicine. The impression that one gains from reading this book is that the general health of the Russian people has improved under the later years of the Soviet regime as well as the average standard of medical service. One also gains the impression which coincides with that of many medical travelers to the Soviet Union that in the scientific and clinical work the workers impress the visitors more with their enthusiasm than with their critical judgment.

This book of Dr. Gantt's can be heartily recommended as both interesting and informative. It belongs to the series, "Clio Medica," edited by E. B. Krumbharr, M.D. RALPH H. MAJOR

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

How to Get Parents' Consents— How one health officer put some quite ordinary health educational measures to work and the good results he got. The moral is that we are not so much in need of elaborate and novel educational technics as we are of using the measures already tried out in the hard school of experience.

CHOPE, H. D. The Rôle of Health Education in a Tuberculosis Testing Campaign. *J. School Health*. 7, 9:211 (Nov.), 1937.

Tuberculosis Goes to College— Sampling the incoming freshmen at a number of important universities it was found that 6 per 1,000 had adult type tuberculosis and that 30 per cent were tuberculin positive. On this basis there must be 6,000 college students with tuberculosis, and a third of a million with some form of tuberculous infection. Among high school students there must be 50,000 cases of tuberculosis. The total cost of tuberculosis in these two groups alone exceeds a hundred million dollars.

FERGUSON, L. H. A Five Year Review of Tuberculosis in College Students. *Am. Rev. Tuberc.* 36, 4:478 (Oct.), 1937.

May This Good Work Go On— This committee points out that some commercial interests are stressing excessively low summer temperatures, permitting too great air velocities, and failing to employ dehumidifying devices. Comfort and health alike are jeopardized. You're telling us, committee!

HAYHURST, E. R., *et al.* Equipment for Air Conditioning. *A.J.P.H.* 109, 22:1802 (Nov. 27), 1937.

As Guards Go Down— Of a thousand plus students entering a middle-west university more than a quarter had not been vaccinated; a third had only slight immunity; 61 per cent were in some degree susceptible to smallpox. Not a wholesome picture.

HUSBAND, M. W., and LOY, D. T. Immunity to Smallpox. *J.A.M.A.* 109, 22:1797 (Nov. 27), 1937.

Continuing Southern Sanitary Problem— Sampling the rural population in North Carolina, a hookworm infestation incidence of 12 per cent among the whites was revealed. In the same counties the Rockefeller Sanitary Commission found a 36 per cent incidence some twenty-five years ago. It is evident that much work remains to be done before the last worm is unhooked.

KELLER, A. E., *et al.* The Present Status of Hookworm Infestation in North Carolina. *Am. J. Hyg.* 26, 3:437 (Nov.), 1937.

While School Children Are Weighed and Measured— Though commending the arm-girth, chest-depth, hip-width measures, the author points out that they, like other methods of judging nutritional status, have their limitations, but come closest to measuring the true health of the child.

KLEINSCHMIDT, E. E. What Standards Should Be Used in Determining the Nutritional Status of School Children? *J. School Health*. 7, 9:216 (Nov.), 1937.

Educating Health Workers— Three projects for continuing staff education are under way in Kentucky. The first group is the state department personnel, the second, the county health

workers, and the third is for allied groups, physicians, nurses, educators, social workers, etc. Each project has a separate committee carrying out independent plans.

McCORMACK, A. T., and HARRIS, R. F. Kentucky's Plan for Public Health Education. *Pub. Health Rep.* 52, 44:1530 (Oct. 29), 1937.

Last Word in Diphtheria Prophylaxis—Although we have not yet sufficient evidence to determine the one best way to immunize against diphtheria, the man who should know most about the subject suggests that two doses, one of alum precipitated and one of fluid toxoid will give the best results.

PARK, W. H. Duration of Immunity Against Diphtheria Achieved by Various Methods. *J.A.M.A.* 109, 21:1687 (Nov. 20), 1937.

Leadership for Modern Health Objectives—Although the Surgeon General was speaking to nurses, his discussion applies equally to other public health workers and should be required reading for all. He said that until research produces new knowledge, it is by striving against syphilis, tuberculosis, cancer, pneumonia, infant and maternal mortality that the greatest savings in mortality can be made. Far more use of public health nursing should be made than has been made in the past.

PARRAN, T. Public Health Nursing Marching On. *Pub. Health Nurs.* 29, 11:617 (Nov.), 1937.

About V. D.—How venereal diseases are combated on a grand scale in New York City is told by the health officer. The plan includes vastly increased diagnostic and treatment services, epidemiologic investigations, educational activities, and reporting.

RICE, J. L. Combating Syphilis and Gonorrhea. *New York State J. Med.* 37, 21:1822 (Nov.), 1937.

School Health Education By Whom?—Suppose a group of orthopedists decided that the children under their care needed some general educational services, so they call in an educator to the hospital at the beginning of the year to tell them what to do about their educational problems. Would the school man be flattered? Would he feel that the problem could be solved so? It is high time, the author says, to stop talk and to begin doing in the matter of preventive medicine in the school program.

SMILEY, D. F. The Preventive Medical Versus the Physical Training Approach to School Health Problems. *J. School Health.* 7, 9:214 (Nov.), 1937.

Heaven Lies About Us in Our Infancy—Providing a time table for physicians who may want to immunize the helpless infants, among the families in their practice, against smallpox, diphtheria, scarlet fever, pertussis, and typhoid fever, the authors consider the addition of a tuberculin test to the lengthening list of punctures.

ASSOCIATION NEWS

EXECUTIVE BOARD MEETING

THE following is a brief resumé of the discussions and actions of the Executive Board at its meeting on December 17.

There were present:

John A. Ferrell, M.D., *Chairman*

J. N. Baker, M.D.

Louis I. Dublin, Ph.D.

John P. Koehler, M.D.

Arthur T. McCormack, M.D.

Thomas Parran, M.D.

John L. Rice, M.D.

Huntington Williams, M.D.

Abel Wolman, Dr.Eng.

Reginald M. Atwater, M.D., *Executive Secretary*

The appointment of Gregoire F. Amyot, M.D., D.P.H., as Administrative Associate in the study of State Health Facilities, effective January 1, 1938, was confirmed. Dr. Amyot was formerly Assistant Health Officer, Provincial Board of Health, Vancouver, B. C., Canada.

The 1939 Annual Meeting city will be selected from the Central or the Northeast area. The cities in the Central area are Louisville, Chattanooga, Columbus, Cincinnati, and Pittsburgh. Those in the Northeast area are Baltimore, Washington, Newark, Philadelphia, New York City, and Atlantic City.

New appointments of Fellows to the Committee on Research and Standards were confirmed as follows:

Margaret G. Arnstein, R.N. (1940)

Richard A. Bolt, M.D. (1940) reappointment

Walter S. Frisbie (1938)

A. Parker Hitchens, M.D. (1940)

John F. Norton, Ph.D. (1940) reappointment

Clair E. Turner, Dr.P.H. (1940) reappointment

As provided in the By-laws, the following appointments were made by the

Sections indicated to the Committee on Eligibility and were confirmed. These terms expire in 1939.

Mary V. Dempsey, Vital Statistics Section
Emery R. Hayhurst, M.D., Industrial Hygiene Section

George D. Lummis, M.D., Health Officers Section

Agnes J. Martin, R.N., Public Health Nursing Section

Charles F. Wilinsky, M.D., Child Hygiene Section

The Executive Board considered and approved a long list of appointments to Association and Section Committees to be published in full in the 1937-1938 *Year Book*.

C. C. Young, Dr.P.H., Director of Laboratories, State Department of Health, Lansing, Mich., was declared elected to fill a vacancy on the Governing Council, with term expiring in 1938.

Approval was given to the request of the Health Officers Section for conducting an Institute for Health Officers in connection with the Kansas City Annual Meeting.

A progress report was received from the Exploratory Committee of the Executive Board charged with a study of the Public Health Aspects of Medical Care.

The Executive Secretary was empowered to appoint a committee to serve with the Section Secretaries as a Program Committee.

A plan governing the publication of the *American Journal of Public Health* was approved and an Editorial Board of five Fellows was named. These selections will be announced when acceptances have been received. Dr. Mazýck P. Ravenel was designated Editor, and the Executive Secretary was appointed Managing Editor.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Asa Barnes, M.D., Kennett, Mo., District Health Officer, State Board of Health
 John W. E. H. Beck, M.D., State Health Dept., Austin, Tex., Director, Local Health Services
 William R. Cameron, M.D., C.P.H., King St., Hagerstown, Md., Washington County Health Officer
 Bernard Greenberg, M.D., 1934 Bergen St., Brooklyn, N. Y., Borough Chief, Bureau of Preventable Diseases, New York City Department of Health
 Robert M. Matts, M.D., Box 207, Yuma, Ariz., Director, Yuma County Health Service
 Henry G. Steinmetz, M.D., 104 S. Indiana Ave., Bloomington, Ind., Director, District Health Department, State Board of Health
 Thomas L. Waggoner, M.D., 203 S. Park, San Angelo, Tex., Director, District Health Dept., State Department of Health

Laboratory Section

Raul Ferramola, Corrientes 4317, Buenos Aires, Argentina, S. A., Bacteriologist, Obras Sanitarias de la Nacion
 Archibald M. Fitz-Randolph, 915 Fifth Ave., Asbury Park, N. J., Bacteriologist, Monmouth County Local Health Unit #1
 Agnes C. Hamann, 333 E. 68 St., New York, N. Y., Laboratory Assistant, Dept. of Health
 Dora Snyder, City Laboratory, Lubbock, Tex., City Bacteriologist
 Eugenio Suarez, M.D., Instituto Bacteriologico, Santiago, Chile, S. A., Director

Vital Statistics Section

John P. Mills, 393-7th Ave., New York, N. Y., Assistant Superintendent, Equitable Life Assurance Society
 Edward S. Weiss, 329 Catherine St., Ann Arbor, Mich., Student

Public Health Engineering Section

Clayton H. Billings, Floydada, Tex., District Sanitarian, State Dept. of Health
 Frank J. Brands, 388 St. Johns Place, Brooklyn, N. Y., Veterinarian, Dept. of Health
 Leigh I. Holdredge, 27 Ford Ave., Oneonta, N. Y., District Sanitary Engineer, State Dept. of Health
 Robert F. Killeen, 702 E. Ellsworth St., Mid-

land, Mich., Sanitarian, Midland County Health Dept.

Leonard A. Lankford, County Health Dept., Dallas, Tex., Sanitarian
 Albert W. Petty, 201 Haughton St., Williamston, N. C., District Sanitarian, State Board of Health
 Vernon G. Wait, 465 W. Huron St., Pontiac, Mich., City Sanitarian

Industrial Hygiene Section

Nehemiah Janko, M.D., 25 Marble Hill Ave., New York, N. Y., Practising Physician

Food and Nutrition Section

Edward A. Crawford, 415 N. Caroline St., Herkimer, N. Y., Inspector of Foods, New York City Dept. of Health
 Harry D. Kruse, M.D., Sc.D., 40 Wall St., New York, N. Y., Nutrition Survey, Milbank Memorial Fund
 Flavius A. Newkerk, 52 Watkins Ave., Middletown, N. Y., Inspector of Foods and Drugs, New York City Dept. of Health
 Meyer Schubert, 601 W. 162 St., New York, N. Y., Inspector of Foods, Dept. of Health

Child Hygiene Section

Richard F. Boyd, M.D., State Board of Health, Topeka, Kans., Assistant Director, Division of Child Hygiene
 Ernest Buffone, M.D., 1705-78 St., Brooklyn, N. Y., Medical Inspector, School Hygiene, Dept. of Health
 Van C. Tipton, M.D., 812 Avondale Rd., Austin, Tex., Field Director, Maternal and Child Health, State Dept. of Health

Public Health Education Section

Weyman C. Huckabee, 323 Zakoba Machi, Hiroshima, Japan, Director, Fukushima Cho Public Health Center (At present—Student at Yale University)
 Milton I. Levine, M.D., 41 W. 96 St., New York, N. Y., Director of Study on Tuberculosis Immunization, Bureau of Laboratories, Dept. of Health
 Vonda M. Roach, 118 W. Shaw, Tyler, Tex., Nurse, Tyler-Smith County Health Unit
 Mildred Schpeiser, 655 Barbey St., Brooklyn, N. Y., Health Education Worker, Queensboro Tuberculosis and Health Association
 Verna L. Stanford, 118 W. Shaw, Tyler, Tex., Nurse, Tyler-Smith County Health Unit

Public Health Nursing Section

- Bertha L. Allwardt, 333 E. 30 St., New York, N. Y., Nursing Field Representative for New York State, American Red Cross
- Gladys L. Crain, R.N., 81 Strathmore Rd., Brighton, Mass., Nurse Epidemiologist, State Dept. of Public Health
- E. Hazel Golly, 711 N. Jay St., Rome, N. Y., State Staff Nurse, State Dept. of Health
- Anna E. O'Brien, R.N., 1310 State St., Schenectady, N. Y., General Director, Public Health Nursing Association of Schenectady County
- Lucille Perozzi, R.N., 816 Oregon Bldg., Portland, Ore., Educational Director, Division of Public Health Nursing, State Board of Health
- Anna L. Pick, 42 S. Grand St., Cobleskill, N. Y., County Nurse
- Frances A. Valliant, R.N., 1421 Madison Ave., New York, N. Y., Student at present
- Mary J. Wallace, 1917 Washtenaw, Ann Arbor, Mich., County Nurse, Michigan Dept. of Health
- AuVerne Ware, R.N., 726 N. Beacon St., Dallas, Tex., County Public Health Nurse

Margaret M. Whalen, R.N., 65 Broad St., Rochester, N. Y., District State Supervising Nurse, State Dept. of Health

Epidemiology Section

- Harry S. Lichtman, M.D., 8735 Bay Parkway, Brooklyn, N. Y., District Diagnostician, Dept. of Health
- Harold M. Williams, M.D., City Hall Annex, Fort Worth, Tex., Epidemiologist, Dept. of Health

Unaffiliated

- Alfred Koerner, M.D., 53 E. 96 St., New York, N. Y., Inspector, Dept. of Health
- John Neilson, Jr., M.D., 122 E. 42 St., New York, N. Y., General Practitioner
- Paul T. Salchow, M.D., 956 Pingree Ave., Detroit, Mich., Student at present
- Wells O. Stephens, Jr., D.D.S., Gregg County Health Unit, Longview, Tex., Director of Dental Service
- Allan A. Twichell, 310 Cedar St., New Haven, Conn., Technical Secretary, Committee on Hygiene of Housing, American Public Health Association

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS AVAILABLE

The U. S. Civil Service Commission announces an unassembled examination for the positions of Principal Consultant in Child Welfare Services at \$5,600 a year, and Principal Consultant in Medical Social Work for

Children at \$5,600 a year. Applications must be on file by January 10. Circular No. 3 may be obtained from the Civil Service Commission in Washington or any first class post office.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist, and teacher, now employed, with C.P.H. from Johns Hopkins and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., Johns Hopkins; public health course at Michigan; experienced in school and city health work, will consider an administrative post in eastern United States. A354

Physician, M.D., Western Reserve; short course for health officers, Johns Hopkins; with county and state experience, wishes administrative or epidemiological position; north or west preferred. A349

Physician, M.D., Yale, completing M.P.H. at Columbia; good clinical background; will consider appointment in child health, epidemiology or public health administration. A350

Physician, M.D., Northwestern University; Dr.P.H., Yale; will consider appointment in general administration, infant welfare or epidemiology. A300

Experienced Health Officer who has completed Vanderbilt short course, 1936, will consider appointment. West preferred. A320

Physician, M.D., University of Maryland; C.P.H., Johns Hopkins; broad experience in county public health administration, will consider opening of better class. A346

CHILD HYGIENE

Woman physician, M.D., Rush Medical; Wishes administrative or clinical position in maternal and child health. C347

Woman physician, M.D., Yale; Dr.P.H., Yale; experienced in pediatrics and administration of state bureau, will consider attractive opening. C348

STATISTICIAN

Young man with 8 years' experience in public health statistics in well known national organization, and degree in Business Administration, now employed, will consider statistical position or combination with office administration. A310

MISCELLANEOUS

Dentist, graduate of Temple University, with excellent post-graduate experience, desires position in administrative aspects of dental hygiene. M352

Woman with excellent preparation and wide experience in health education field; organization, administration, supervision and program-making in city, rural and state work. Now employed but would consider good opportunity. \$3,500 minimum. M316

Bacteriologist with training at C.C.N.Y., N.Y.U. and Cornell Medical College, wishes laboratory position in bacteriology; East or Southwest. M351

Experienced teacher, B.S., Massachusetts Institute of Technology; graduate courses Harvard School of Public Health, wishes teaching position or will consider statistical or health education opportunity. M353

NEWS FROM THE FIELD

UNITED STATES CONFERENCE OF MAYORS

THE United States Conference of Mayors made public the report of its National Health Officers Qualifying Board created early in 1937 under a resolution enacted at the 1936 Annual Conference. This board, consisting of leading public health authorities of the United States, was established for the specific purpose of formulating the professional qualifications which commissioners of public health in the larger cities of the nation should have. The job was undertaken as the first step in the long-term program of the Conference of Mayors in improving the professional qualifications for those who hold important municipal offices throughout the country.

The membership of the National Health Officers Qualifying Board of the Conference of Mayors is as follows:

Joseph W. Mountin, M.D.,* *Chairman*
Allen W. Freeman, M.D.*
John L. Rice, M.D.*
Wilson G. Smilie, M.D.*
Huntington Williams, M.D.*
Carl V. Reynolds, M.D.†
Edward S. Godfrey, Jr., M.D.*

The committee's report, which has been awaited by the medical and public health professions, provides for the following technical qualifications for chief municipal health officers:

QUALIFICATIONS FOR CITY HEALTH OFFICERS

Grade I

(Applicable, in general, to cities of 500,000 population and over.)

The minimum qualifications for health officers in this class shall consist of:

* Fellow A.P.H.A.
† Member A.P.H.A.

Graduation in medicine from a Grade A Medical School and not less than 6 years' full-time experience in public health work, 3 years of which must be in a responsible administrative position; 2 of the 3 years of general experience may be substituted by a course in public health of not less than 1 scholastic year in residence at a recognized institution of learning.

Grade II

(Applicable, in general, to cities of from 100,000 to 500,000 population.)

The minimum qualifications for health officers in this class shall consist of:

Graduation in medicine from a Grade A Medical School and not less than 4 years' full-time experience in public health work, 1 year of which must be in a responsible administrative position; 2 of the 3 years of general public health experience may be substituted by a course in public health of not less than 1 scholastic year in residence at a recognized institution of learning.

Grade III

(Applicable, in general, to cities under 100,000 population.)

The minimum qualifications for health officers in this class shall consist of:

Graduation in medicine from a Grade A Medical School and not less than 2 years of full-time experience in public health work, or, 1 year of such full-time experience and the completion of a course in public health of not less than 1 year in residence at a recognized institution of learning.

The board will act, at the request of any city, to determine whether candidates for the office of health commissioner, possess the qualifications adopted by the board. If so, the board will certify to the city this fact.

It is noteworthy that the qualifications for public health officers for the first time impose definite and specific medical and *public health* training and experience.

President LaGuardia, in commenting on the report, said:

"We are now beginning to make progress. If every city will adopt the recommendations now made by our special public health committee, we can avoid having the so-called "pill doctor" or the family physician appointed to the important office of Commissioner of Health. Public health administration involves factors requiring personnel with *public health* experience and not only just general medical training. Consequently, if we can establish accepted standards or qualifications which all persons must have who seek the highest public health position in a city, we are insuring a real merit system.

"We have taken public health first because we have had the coöperation of the public health profession itself. We shall next establish committees in other fields—finance, fire, police, etc., and endeavor to develop qualifications for the major posts in the municipal service in these fields. Reformers have been talking for fifty years about the merit system. But it has remained for the mayors, acting collectively, to make the first real contribution in professionalizing the public service, in so far as the highest municipal offices are concerned."

The following resolution was passed:

QUALIFICATIONS FOR MUNICIPAL HEALTH OFFICERS

WHEREAS, the United States Conference of Mayors has now received the report of its committee of seven outstanding public health authorities, and

WHEREAS, this report sets up standard professional qualifications for Commissioners of Health in the larger cities of the country, therefore be it

RESOLVED, that the United States Conference of Mayors recommend to the cities of the country that the suggested standard qualifications for health officers be followed by all cities when appointments to the office of Health Commissioner are made in the future.

CONFERENCE ON MATERNAL AND CHILD WELFARE

A CONFERENCE on the theme of "Better Care for Mothers and Babies" has been called by Katharine

F. Lenroot,[†] Chief of the Children's Bureau, U. S. Department of Labor, to be held in Washington, D. C., January 17-18.

The Planning Committee appointed for the conference includes representatives of many national agencies, among them the American Public Health Association.

Miss Lenroot states that the problem of maternal care and care of the newborn continues to be a matter of grave concern to the people of this country. No matter what method of statistical procedure is used to assign cause to maternal deaths, the United States retains an exceedingly high maternal mortality rate as compared with other countries. In 1935 the number of maternal deaths due directly to pregnancy and childbirth was 12,544. Additional deaths of pregnant women due to other primary causes raised the total number to 14,296. The number of stillbirths in 1935 was 77,119, and the number of babies dying in the first month of life as the result of causes arising during pregnancy or at time of delivery was 56,262. This means that the total number of deaths of mothers, stillbirths, and deaths of babies in the first month of life from causes associated with maternal conditions was 147,677 for the single year of 1935.

The forthcoming conference will canvass in a broad way the resources now available and the work now being done in behalf of mothers and babies throughout the country through the coöperative efforts and under the leadership of the medical profession, public health officials, nursing organizations, professional and lay groups, and interested individuals. It should furnish an opportunity for fruitful discussion and sound planning.

* Fellow A.P.H.A.

† Member A.P.H.A.

PNEUMONIA FILM

A NEW film on pneumonia, "A New Day," has been made in Hollywood by a professional cast. It had its premier public showing at the Radio City Music Hall in New York, December 16.

The new picture was sponsored by the U. S. Public Health Service and produced by the Metropolitan Life Insurance Company. It is introduced by a brief talk by New York City Health Commissioner John L. Rice.*

PNEUMONIA ADVISORY COMMITTEE

TO plan a program for pneumonia control on a national scale, Thomas Parran, M.D.,* Surgeon General of the U. S. Public Health Service, recently appointed an Advisory Committee, which held its first meeting November 12, in Washington, D. C.

Members of the Committee are:

Donald B. Armstrong, M.D.,* Metropolitan Life Insurance Company, New York, N. Y.

David P. Barr, M.D., Washington University School of Medicine, St. Louis, Mo.

Russell L. Cecil, M.D., Cornell University Medical School, New York, N. Y.

Lloyd D. Felton, M.D.,† Johns Hopkins University School of Medicine, Baltimore, Md.

Alfred Friedlander, M.D.,† University of Cincinnati College of Medicine, Cincinnati, O.

Roderick Hefron, M.D.,† Commonwealth Fund, New York, N. Y.

Ernest E. Irons, M.D., Rush Medical College, Chicago, Ill.

Roger I. Lee, M.D., Consultant in Internal Medicine, Boston, Mass.

George H. Ramsey, M.D.,* New York State Department of Health, Albany, N. Y.

Y.M.C.A. SYPHILIS CAMPAIGN

THE National Council of the Young Men's Christian Association has issued a bulletin urging local units to coöperate with physicians and health officials in the drive against syphilis.

The local units are urged to take specific steps for investigation, education and arrangements with physicians for Wassermann tests.

NEW MEXICO PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

THE following new officers were elected by the New Mexico Public Health Association at its annual meeting held in November:

President—William W. Johnston, M.D.,* Las Vegas, N. M.

Vice-President—Helen B. Fenton, R.N.

Secretary-Treasurer—James R. Scott, M.D., Ph.D.,* Albuquerque, N. M.

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

THE Pennsylvania Public Health Association has elected new officers as follows:

Honorary President—Edith MacBride-Dexter, M.D.,† Harrisburg, Pa.

President—John M. J. Raunick, M.D.,* Harrisburg, Pa.

First Vice-President—Harold H. Keller,† Philadelphia, Pa.

Second Vice-President—H. W. Banks, M.D., Prospect Park, Pa.

Secretary-Treasurer—Arthur M. Dewees,† Philadelphia, Pa.

Executive Secretary—Thomas Shriver.

Representative to the Governing Council, A.P.H.A.—Henry Field Smyth, M.D., Dr.P.H.,* Philadelphia, Pa.

FLORIDA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

THE Florida Public Health Association elected the following new officers for 1938 at its recent annual meeting:

President—N. A. Upchurch, M.D.,* Jacksonville, Fla.

First Vice-President—L. J. Graves, M.D., Tallahassee, Fla.

Second Vice-President—Lalla M. Goggans, R.N.,† Jacksonville, Fla.

Secretary-Treasurer—Edward M. L'Engle, M.D.,† Jacksonville, Fla.

Representative on A.P.H.A. Governing Council—William H. Pickett, M.D.,* Pensacola, Fla.

* Fellow A.P.H.A.

† Member A.P.H.A.

SOUTHERN BRANCH A.P.H.A.

ELECTS OFFICERS

AT its Sixth Annual Meeting, the Southern Branch of the American Public Health Association elected the following new officers:

President—James A. Hayne, M.D.,* Columbia, S. C.

First Vice-President—H. A. Kroeze, B.C.E.,† Jackson, Miss.

Second Vice-President—Frances F. Hagar, R.N.,* Nashville, Tenn.

Third Vice-President—Martin R. Beyer, M.D.,† Oklahoma City, Okla.

Secretary-Treasurer—G. Foard McGinnes, M.D.,* Richmond, Va.

NEW JERSEY HEALTH ASSOCIATION

AT the Sixty-third Annual Meeting of the New Jersey Health and Sanitary Association, held at Princeton, N. J., December 10–11, new officers were elected as follows:

President—William H. MacDonald, M.S.,† Trenton, N. J.

First Vice-President—Joseph R. Morrow, M.D., Ridgewood, N. J.

Second Vice-President—Leverett D. Bristol, M.D., Dr.P.H.,* New York, N. Y.

Third Vice-President—L. Van D. Chandler,* Hackensack, N. J.

Secretary—Edward Guion, M.D.,* Northfield, N. J.

Treasurer—Budd H. Obert,* Asbury Park, N. J.

John Hall, B.S.,* of Freehold, N. J., continues as Executive Secretary.

MICHIGAN PUBLIC HEALTH ASSOCIATION

ELECTS OFFICERS

AT its recent annual meeting, new officers of the Michigan Public Health Association were elected as follows:

President—Carleton Dean, M.D., C.P.H.,* Charlevoix, Mich.

Vice-President—John L. Lavan, M.D.,* Grand Rapids, Mich.

Secretary-Treasurer—Marjorie Delavan,* Lansing, Mich.

Representative on A.P.H.A. Governing Council—C. C. Slemons, M.D.,* Lansing, Mich.

PERSONALS

Central States

VICTOR E. LEVINE, M.D., Professor of Biological Chemistry and Nutrition and head of the Department, Creighton University School of Medicine, Omaha, Nebr., has established a medical and biological laboratory in the Arctic, at Point Barrow, Alaska, as a coöperative research project of the U. S. Public Health Service and Creighton University. Dr. Levine, with an Assistant, DELBERT F. FOORD, of the University of California, arrived in Alaska in August and expects to remain a year.

HUGH B. ROBINS, M.D.,† of Marshall, Mich., Associate Director of the Calhoun County Health Department, has been placed in charge of the Department, succeeding DR. MATTHEW R. KINDE,† who is now at the W. K. Kellogg Foundation, Battle Creek.

DR. CHARLES B. STEPHENS, of Iola, Kans., has been appointed Health Officer of Topeka.

Eastern States

HAZEL DUDLEY, R.N., has become Director of the Division of Public Health Nursing in the Connecticut State Department of Health, as of December 1. Miss Dudley previously was on the staff of the Henry Street Nursing Service, New York, N. Y.

CHARLES KURTZHALZ, of Chester, Pa., formerly Executive Secretary of the Delaware County Tuberculosis Association, has been appointed Executive Director of the Philadelphia Health Council and Tuberculosis Committee, to succeed the late HARVEY D. BROWN, PH.D.†

ANNA L. TITTMAN, R.N.,† Vocational Secretary for Public Health Nursing, Joint Vocational Service, New York,

* Fellow A.P.H.A.

† Member A.P.H.A.

N. Y., has become the Executive Director of the Nurse Placement Service, 8 South Michigan Boulevard, Chicago, Ill., as of January 1.

Southern States

DR. GEORGE W. BAKER, of Walters, Okla., has been appointed Health Superintendent of Cotton County.

MONROE F. BROWN, M.D.,† of Fayetteville, Tenn., has been appointed to succeed FRANK L. ROBERTS, M.D.,† as Health Officer of Gibson County, with headquarters in Trenton.

DR. CHARLES M. COLE, of Chatom, Ala., has been appointed Health Officer of Washington County, succeeding DR. ISAAC C. SUMNER, of Chatom.

DR. WARREN A. COLTON, Clinical Director of the Veterans' Administration Facility, Kecoughtan, Va., has been named Chief Medical Officer, to succeed DR. EDWARD N. SCHILLINGER, who was recently transferred to Atlanta.

DR. EVA F. DONGE, of Winston-Salem, N. C., has been appointed to direct and organize antepartum clinics throughout Alabama for the Alabama State Department of Health. Headquarters will be in Montgomery, Ala.

DR. HARVEY C. HARDEGREE, recently on the staff at Excelsior Springs, Mo.,

has been appointed Clinical Director of the Veterans' Administration Facility, of Kecoughtan, Va., to succeed DR. WARREN A. COLTON.

DR. JESSIE M. HARRIS, of Wilberton, Okla., has been appointed Health Superintendent of Latimer County.

JAMES G. MCALPINE, PH.D.,† has resigned as Director of Laboratories, Alabama State Department of Health, Montgomery, Ala.

DR. SHADE D. NEELY, of Muskogee, Okla., has been appointed Health Superintendent of Muskogee County, to succeed DR. CHARLES E. WHITE, of Muskogee.

DR. GAPP M. RUSHING, of Durant, Okla., has been appointed Health Superintendent of Bryan County, to succeed DR. HENRY B. FUSTON, of Bochito.

DR. ISAAC C. SUMNER, of Chatom, has been appointed Assistant to the Health Officer of Mobile County, Ala.

DEATHS

FRANCIS B. GRINNELL, M.D., of the Department of Bacteriology and Immunology, Harvard University Medical School, Boston, Mass., Bacteriologist, died in England in November.

CHARLES E. KAUFMAN, M.D.,† Health Officer of West Haven, Conn., died December 3, at the age of 51.

* Fellow A.P.H.A.

† Member A.P.H.A.

Health Education for the Millions*

LOUIS I. DUBLIN, PH.D., F.A.P.H.A., AND
HOMER N. CALVER, F.A.P.H.A.

Acting Chairman and Secretary, Committee on American Museum of Hygiene, American Public Health Association, New York, N. Y.

WE propose in this paper to discuss certain new procedures and technics in the field of health education. We have in mind the Museum of Hygiene as an instrument and will take this opportunity also to record the progress made in recent years in approaching this objective as a practical, functioning, educational institution.

We need not review here the immense literature on health education. We all know how continuous has been the effort to bring home to the great mass of people the knowledge necessary for avoiding disease and prolonging life. Somehow or other, we have not fully succeeded. We still pay a toll of at least a week of serious illness per capita each year. In addition, there is an unmeasurable but very serious loss of efficiency resulting not so much from clear-cut physical disability but from that hazy state in which a large part of our people find themselves wherein the body does not function well, where the joy of robust health is lacking.

Diseases we know perfectly well how to eliminate such as smallpox, diphtheria, typhoid fever, and malaria still cause serious inroads on health and life. In some areas, they continue to constitute a first class public health problem. Tuberculosis and pneumonia can be greatly reduced in their ravages. Altogether, at least 10 years can be added to the expectation of life of each newborn child if we could but get to the people the knowledge which the advances of science have given us and if this knowledge could in some way be converted into appropriate action.

Earlier, the difficulty was primarily that we did not know the causes of diseases and of premature breakdown nor the channels through which these causes operated. In more recent years with an enormous accumulation of information and with increased public and private health facilities, the problem has been one primarily of distribution, namely, bringing to the great mass of people the benefits of the discoveries in the laboratory and from the current practice of medicine and public health. The school, the newspaper and maga-

zine, and the spoken word, all have served and there is today a more widespread understanding of the principles of personal and social hygiene than ever before. Yet we have failed in bringing this knowledge and service to a very large part of our population. We have clearly underestimated the size of the job to be done. We have not reached the homes of the great mass of the common people. We must break the bottleneck in the flow of information from the laboratory and the clinics to the masses.

The fact is that the American people have not yet assimilated the spirit or content of the great achievements in medicine and in public health work. There are such sobering facts as the enormous growth of the Christian Science movement which clearly indicts our educational institutions for ineffective methods of teaching, and there are other evidences of crass ignorance, superstitions, and gullibility, as indicated by the size and profits of the business of quacks and nostrum venders. These facts, strikingly characteristic of our American life, show how far we still have to go in bringing home to the people the scientific basis upon which medicine and public health rest. We must find new ways.

We believe that the answer lies very largely in developing the mechanism of visual education. The eye is primarily the source of our increasing familiarity with the modern world. But we must not only see, we must handle. The educators know that the appeal must be to as many senses as we have in order to arouse interest, to hold attention, and for knowledge to become a part of us. We must develop a new mechanism on a huge scale for public health education. We believe that the answer lies in the methods of the modern museum.

Our Association took a very definite stand in this direction some years ago

when it appointed the Committee on the American Museum of Hygiene which was to investigate the subject and take the necessary steps which would lead to the establishment of Museums where the experiment could be tried to discover the methods by which the mass of knowledge in the field of medicine and public health could be more effectively brought home to the people. We have made some progress in this direction and our paper will be, in a sense, a summary of the present state of the operations of this committee.

For one thing, our committee has been continuously active canvassing and exploring this field and in assembling information. In like manner, we have encouraged other groups to do so in various parts of the country. Today the museum idea is on everyone's tongue.

This year grants were made to the Association for the purposes of the committee by the Carnegie Corporation of New York and the Josiah Macy, Jr. Fund. These made possible the employment of a staff which includes Dr. Benjamin C. Gruenberg who has prepared a well thought out document which will shortly be available for distribution. In this there has been assembled the accumulated information of the committee and the views of leading educators, physicians, and museum executives. A well equipped architect, Woodner-Silverman, has likewise been at work studying the physical problem of housing the exhibits and visualizing for us an ideal institution.

These studies will interest health workers everywhere. They suggest the importance, the means of approach and the possibilities for service for a Museum of Hygiene in their communities.

Running side by side with these efforts our committee has attempted to

pave the way to the establishment of an experimental institution, believing that to create one museum somewhere would be the best way to stimulate the creation of museums everywhere. Obviously in a time of financial depression, it has not been an easy matter to obtain that large sum of money necessary for the building of a museum and the furnishing of it with the expensive laboratories, materials, and personnel which a museum should clearly have. Instead we have utilized such opportunities as have come our way. Taking advantage of our experience with the Century of Progress we took prompt action when the proposal for a New York World's Fair was announced. We saw in this undertaking a unique occasion for an experiment in mass health education. It is conservatively expected that more than 20 million people will pass through the gates of this Fair in 1939. Why not attempt to bring home to these millions the fundamental health knowledge which has been accumulated during the years? Here was a chance to try out various technics. Fortunately, an administration of intelligence and vision at the World's Fair headquarters saw eye to eye with us on the possibilities of this undertaking and has made it possible for us to work with them. The Fair has created an Advisory Committee on Medicine and Public Health drawing on our Museum Committee for personnel and including over 100 representative medical and public health leaders. An Executive Committee of this larger group has been given authority to plan and erect a large and representative exhibit. The Fair Corporation will build a beautiful structure exclusively for medical and public health exhibits and has appropriated a sizable fund to aid the committee in arranging for some of the basic exhibit material.

One of the very first decisions made by the Executive Committee was that

the exhibit on medicine and public health must be planned to present a unified story, avoiding by all means the confusing result of selling space and allotting booths wherever they can be disposed of without reference to the presentation of any coördinated plan. It is not to be expected that a visitor can grasp the essentials of medicine and public health as a whole unless a very definite attempt is made to correlate the various parts of the exhibit. The New York World's Fair Committee on Medicine and Public Health has attempted to solve this problem by aiming for a completely scientific yet dramatic exhibit carefully planned in advance. Space as such will not be sold to commercial exhibitors. The committee has assumed the responsibility for the planning and financing of the entire exhibit. In this way it will from the very outset plan a completely rounded and coördinated presentation. This exhibit will, we believe, be the first attempt in America to produce a full size medical and public health exhibit at once scientifically sound and at the same time properly balanced as to its constituent parts.

The building itself is attractive and is extraordinarily well placed in relation to the chief attractions of the Fair. In all, there will be 80,000 square feet of space, making possible for exhibit purposes a net of a little over 37,000 square feet. We have divided our building into 4 main sections. There will be first a central Hall of Man, with a large focal exhibit on the human body in its normal functioning. Here will be demonstrated the anatomy and physiology of man, the dynamics of his various bodily functions, growth and reproduction, the glands of internal secretion and the organs of special sense. The problem of man's origin and his possible improvement will be considered. Exhibits in this hall will be similar to those which have been

developed by the German Hygiene Museum in Dresden, although many new models and features will be introduced.

Beyond the Hall of Man will be the Hall of Medical Science and the Hall of Public Health. Each of these halls has been divided into some 20 or more sections. The location of these sections between the two halls has been more or less arbitrary, although in general those which are principally medical have been assigned to the Hall of Medical Science, and those principally in the field of public health have been assigned to the Hall of Public Health. It is expected, however, that each subject will be treated in both its medical and public health aspects wherever it is located. In view of the limited space available, it will obviously not be possible to provide room for everything, and duplication must be avoided. The subjects selected for these sections are those which have seemed to the Executive Committee to be the most important. Such topics as the following have already been decided upon. In the Hall of Medicine, they are cancer, the filterable viruses, the common cold and influenza, pneumonia, tuberculosis, diabetes, the degenerative diseases of old age, heart disease, hospitals and the organized care of the sick, dentistry and oral hygiene, medical education, roentgenology, pharmacology and a number of allied topics. In the Hall of Public Health, sections will be devoted to health administration, the control of communicable diseases, tropical disease, children's diseases, maternal health, mental hygiene, industrial hygiene, safety, sanitary engineering, milk and food control, the conservation of sight, hearing and speech, superstitions, and finally a section devoted to a public health library and to an information service. The fourth main sub-division will be a theatre of hygiene, where a continuous program of lectures, demon-

strations, and motion pictures will be given.

Each of these sections, amounting in all to about 50, will be under the supervision of a special sub-committee whose duty it will be to formulate plans for the exhibit in the special field with which it is concerned. The committees will deal primarily with subject matter rather than with methods of presentation. Each committee is being asked to state what are the outstanding non-controversial facts in its field which it believes the public should be told. And we have been extremely fortunate with our group of committeemen and committee chairmen. They make up a literal "Who's Who" in medicine and public health. We can be assured that their labors will bring into sharp relief the most important and interesting information in their fields. To give us an interesting and instructive presentation of the facts, we have brought together a group of exhibit experts and technicians of outstanding training and experience. They will know how to tell our story so dramatically and persuasively as to justify the enormous labor which this project will entail by the scientific committees.

The problem of financing this exhibit has received our careful attention. It is the belief of the Executive Committee that there are a considerable number of large and ethical commercial and non-commercial organizations which have such an important stake in having the facts of medicine and public health presented dramatically to the public that they will be willing to sponsor these exhibits and to defray their cost. Already, from contacts made and from the reactions of a considerable number of such organizations, we have reason to believe that our plan of financing through sponsorship will be realized with assurance that our original plan of setting up an exhibit entirely scientific in character and completely

coördinated as to its parts will be carried out. There is then an important departure from tradition in that this exhibit is planned on the basis of a presentation of subject matter rather than on the exploitation of products or organizations.

Our experience with the medical exhibit at the Fair, we hope, will lay the foundation for the establishment of our much hoped for American Museum of Hygiene. We believe that our exhibit will be so excellent that there will be a spontaneous demand to keep the materials intact and to exhibit them in a permanent institution—the first American Museum of Hygiene. This, of course, is our ambition; only time will prove the extent to which we are justified in our faith.

We have already in the discussion of our plans for the World's Fair exhibit outlined pretty much what are the chief characteristics of this permanent Museum of Hygiene. Briefly to recapitulate, we have in mind for such a museum a dynamic approach to the problem how to teach the average man and woman what they should know about their own physical organization; how the progress in medicine and public health affects them personally; and how they can make for themselves a better and more healthful life. Certainly this museum is not conceived in the old sense as a mausoleum for old bric-a-brac. It is rather a modern laboratory of health education. Its methods include the use of three dimensional materials, moving objects, and all other modern technics. It will experiment with new methods and new materials. It will attempt continuously to evaluate its own work and to serve the health educational field generally, including the education of adults as well as children—all social and economic strata—the various industries and professions.

There is really no reason why those of us who are in the field of public

health education should not take a leaf out of the book of the circus people and capitalize on human curiosity. Why should the selling skills be the property of the nostrum venders, the quacks, and the self-aggrandizing cultists. We can adapt their skills for the service of man and the conservation of health just as well as they can use these skills for his exploitation. Nor are we concerned with a theoretical consideration. The Museum of Hygiene, as we have conceived it here, has already played a very important part in the education of the German people. The museum at Dresden and its exhibitions have after all been in operation 25 years, and have during this time become established, accepted institutions in that country. Every year hundreds of thousands of people flock to its doors. Its services are extended throughout Europe with travelling exhibitions large and small which take its message to additional millions. Sizable revenues are derived from admission fees to these shows. Certainly, the methods evolved by the museum at Dresden and its branches have worked, and there is no reason why they should not succeed equally well in a country like our own where similar conditions prevail as to literacy, innate curiosity, and an emphasis on obtaining knowledge through sight and the other senses.

England also has recognized the importance of mass health education to national well-being. This very month (October) there begins in that country an ambitious program under the direction of the Ministry of Health, which is designed to secure for the people the fullest possible use of all health and medical facilities. The Central Council of Health Education, which coördinates all health education services, official and voluntary, will assist in this campaign, drawing upon its successful experience in teaching health to the masses through the medium of exhibits.

We have then in America a grand opportunity to capitalize on these experiences of our foreign confreres, adapting the best in their programs to our conditions and our psychology, and making our own contributions to further progress in this field. The United States is noted for its development of mass production and mass distribution in many fields. In the field of life conservation, production of knowledge has outstripped distribution.

The warehouses of our knowledge are full to overflowing. The time has come to put this knowledge into the hands of those millions for whom it was produced. We look forward to the next decade, during which time a new piece of machinery for the dissemination of knowledge will be created which we hope will be worthy of the vast sums of money and the patient scientific labors which have been expended in producing this life saving knowledge.

Puerperal Sepsis and Its Prevention

MATERNAL mortality and morbidity, both of which present little evidence of decrease in civilised countries in spite of the improvement in the general health, continue to cause grave concern, not only to obstetricians but also to governments. The principal reaction so far as the latter are concerned has been to institute elaborate statistical enquiries into the causes of death and disablement in childbirth. Many reports on these investigations have now been published comprising, in the aggregate, the statistical study of an enormous number of cases. It must be said, unfortunately, that they have not contributed very much to the solution of the problem. They have merely defined it and its extent but have given little or no indication of how improvement may be obtained.

In the case of puerperal infections, bacteriological research has, however, given somewhat more assistance. We now know that the haemolytic streptococcus is responsible for 39 per cent of the severe cases and for 69 per cent of the deaths which are due to infection. Second in importance are

the anaerobic streptococci which are responsible for 29 per cent of the cases and for 8 per cent of the deaths. Third in order of importance are the coliform bacilli responsible primarily for pyelitis and cystitis which comprise about 20 per cent of the pyrexias associated with childbirth and also for a proportion of uterine infections.

There is now an overwhelming body of evidence showing that the haemolytic streptococci causing puerperal infections are of exogenous origin and derived in most instances from the nasopharynx of an attendant at the time of delivery, occasionally from the patient's own nasopharynx and more rarely infection of some kind in the home.

On the other hand, the anaerobic streptococci are probably of endogenous origin derived from organisms present in the vagina before delivery which are introduced into the uterine cavity by intrauterine manipulation during delivery. The coliform infections are almost certainly derived from the bowel. . . . Ronald Hare, M.D. *Canad. Pub. Health J.*, Dec., 1937.

Scarlet Fever Immunization with Formalinized Toxin*

A Preliminary Report

GAYLORD W. ANDERSON, M.D., F.A.P.H.A.

Massachusetts Department of Public Health, Boston, Mass.

IMMUNIZATION against scarlet fever through the use of the Dick toxin has found but limited application because of the number of the injections required and the severity of the attendant reactions. If this disease is to be attacked through widespread immunization as was diphtheria there is need for an immunizing agent which can be administered without reactions and which will consequently be as readily accepted by the public as is diphtheria immunization. The early reports of Veldee on the use of formalinized toxin were sufficiently encouraging to warrant a more extensive trial. Veldee reported that over 80 per cent of the susceptible children given 3 injections of this solution were rendered Dick negative when retested 1 month after the last injection. After a preliminary observation of this material as used by Veldee in certain Massachusetts institutions permission

was obtained from the Scarlet Fever Committee for its manufacture and use on an experimental basis.

PREPARATION OF FORMALINIZED TOXIN

Toxin is produced by growing the Dochez NY 5 scarlet fever streptococcus in veal infusion broth to which is added 2 per cent dextrose. The growth of the streptococci produces acid from the dextrose, necessitating periodic neutralization with sodium hydroxide. Both the method of adding dextrose and the method of adjusting the reaction of the broth have varied during the study. The potency of the toxin produced has ranged from 150,000 to 200,000 S.T.D. per c.c. The streptococci are removed from the toxin by filtration through paper and Berkefeld filter. The filtrate is incubated at $37\frac{1}{2}^{\circ}$ C. in the presence of 0.4 per cent formalin for approximately 100 days. The fall in residual toxin is followed by means of skin tests on rabbits until a low enough level is reached to permit use of the material. The amount of residual toxin is then accurately determined by skin tests on humans who show positive Dick tests. Each lot has been tested on not less than 12 such individuals; usually more than 12. The residual toxin of lots used in the

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

NOTE: This report is of work carried on jointly by the Divisions of Biological Laboratories and Communicable Diseases, the author appearing merely as the spokesman for the department. Credit belongs to the entire staff of the divisions as well as to the health officials of the various communities and institutions in which these studies have been conducted.

study has varied from 500 to 1,500 skin test doses per c.c. The antigen has been given in doses of 0.1 c.c., 0.5 c.c., and 1.0 c.c. at intervals of 3 weeks, the first 2 doses being diluted to 1 c.c. volume for ease of administration.

METHOD OF STUDY

During the winter of 1931-1932 the use of this material was observed in 3 Massachusetts institutions. As it was then apparent that it could be administered safely and without undue reactions, and that through its use a reasonable proportion of susceptibles were rendered Dick negative, the administration of formalized toxin was made routine in the 3 hospitals for tuberculous children under the auspices of the Massachusetts Department of Public Health. During the winter of 1933-1934 community-wide programs were instituted in Wellesley and East Bridgewater. Similar programs have since been conducted in Bridgewater, Framingham, Gloucester, Greenfield, Rockport, and the towns in the southern Berkshire Health District.

Although no attempt was made to urge parents to have their children tested and given the immunizing agent if found susceptible, the popular acceptance was so great in the communities where it was offered that in some cases more than half of the susceptible school population was given the injections. The high proportion of the child population so immunized may have so influenced the spread of scarlet fever in the community that neither the immunized nor the non-immunized had the usual number of infecting exposures, which would mean that the value of the injections was not being effectively tested. Consequently the later studies in Worcester, Fall River, and Springfield have been planned to reach so small a fraction of the group as to avoid the possibility of interfering with the spread of the disease and thereby re-

ducing the chance of exposure of the immunized children. This selection of a small group for immunization has been accomplished through offering the immunization only in the parochial schools of these cities, leaving the public schools and a portion of each parochial school unprotected. In no community has there been any deliberate selection of children, the injections being given to all children whose parents signed written requests. As these request slips have been distributed to the parents of all children eligible for immunization, the selection has been determined entirely by parental reaction to the request.

In addition to the use of the formalized toxin as above noted, it has been administered to all the susceptible children in some dozen orphanages and children's schools. Similarly it has replaced the use of the Dick toxin for the immunization of nurses in several training schools. No attempt is made at this time to analyze the results in these groups other than to state that with one or two exceptions the institutions have been free of scarlet fever and the nurses' training schools have been uniformly enthusiastic as to the value of the formalized toxin and the freedom from reactions.

In order to achieve uniformity of results, and in keeping with the agreement with the Scarlet Fever Committee, all of the testing and immunizing have been conducted under the immediate supervision of the staff of the Massachusetts Department of Public Health. In all of the community-wide programs the Dick tests have been performed and read by members of the staff, except that in Wellesley and Framingham about 100 children were given the test injections by the family physicians but the results read by a member of the department. With few exceptions the tests have all been read by Drs. Feemster, Gilman, and Poutas.

All of the immunizations were given by or in the presence of staff members. A similar procedure was carried on in orphanages, boarding schools, and nurses' training schools. In the 3 state hospitals for tuberculous children and the 3 schools for feeble-minded children, the preliminary Dick tests and immunizing injections were given by members of the institutional staff, but all subsequent testing was done by the same group as did the testing in the community studies. There is thus a high degree of uniformity of procedure underlying the data here presented.

In carrying on the Dick tests one or two departures have been made from the procedures recommended by the Dicks. The syringes used were sterilized by being boiled in tap water but thoroughly flushed with test toxin before use. Platinum needles were used and flamed in an alcohol lamp before each use. The high percentage of susceptibles found on the original Dick test in certain communities (over 80 per cent in Wellesley) would indicate that these procedures have not seriously affected the accuracy of the readings of the Dick test. All immunizing injections were given with the Vim-Forsbeck apparatus which had been sterilized by boiling in tap water.

In the early studies the Dick test was performed without the benefit of a control injection. It later became apparent that a certain proportion of those immunized with formalinized toxin had a false positive reaction on retest due to the large amount of protein in the solution. Consequently during the latter portion of the studies all retests have been accompanied by a control test on the opposite arm with a toxin solution autoclaved at 120° C. for 1 hour. No child in whom the control test was a deciding factor in classifying it as Dick negative after injection has subsequently developed scarlet fever. Control injections were also given to

a large proportion of the children at the time of the original test before immunization. The number found with a pseudo-reaction before immunization is too small to warrant the routine use of the control test for this group, except perhaps on adults or adolescents.

In determining the attack rate of scarlet fever among the immunized no attempt has been made to check the accuracy of the diagnoses. All cases of scarlet fever reported to the local board of health by physicians have been included in the tabulations. Thus the cases in immunized and non-immunized children are based on the same criteria of diagnosis. In the few cases of scarlet fever in immunized children seen by a representative of the department the findings were such as to warrant reasonable doubt as to the accuracy of the diagnosis. In every such case the diagnosis of scarlet fever was accepted to avoid a possibly biased selection. In several other cases there was also reasonable doubt as to the accuracy of the diagnosis. To have excluded these or to have checked as to accuracy of the diagnosis among the immunized children alone would have rendered the immunized group not comparable with the control.

Exclusive of the institutional and nursing groups, preliminary Dick tests have been given to over 14,000 children, of whom 63 per cent have been found positive. Of those who began the immunizing injections, 8,212 received the complete course of 3 injections.*

In order to calculate the effect of the 3 injections of formalinized toxin in protecting a previously susceptible child against subsequent clinically recognizable scarlet fever, an attempt has

* In addition to the above groups, 7,009 children were tested in Fall River and Springfield late in 1936, and 2,969 given the complete course of 3 injections. These have not been included in the data here reported as they have been in the study only a few months.

been made to calculate risk on the basis of child-months of exposure. Thus an immunized child that has been in the study for 36 months is assumed to have had 36 child-months of exposure. Similarly a child in the same community that was not immunized until 2 years after the beginning of the study is assumed to have had 24 months of exposure as a non-immunized child and 12 months as an immunized. Owing to the variations in risk of scarlet fever at different age levels, all calculations of exposure have been reduced to individual years of life. Thus a child immunized at the age of 5 has a certain number of child-months of exposure as a 5 year old; a year later becomes a 6 year old and has 12 child-months of exposure as such and a year later is calculated as a 7 year old. In each community the calculation dates back to the time when the program began in that particular community. Thus in Wellesley where the work began late in 1933, both immunized and control groups have been observed longer than in a community such as Greenfield where the study did not begin until 1935.

A child has been considered as immunized 3 months after the last injection. During the course of the immunization and the 3 subsequent months it has been carried in the non-immunized group. Similarly an immunized child has been considered as one who has received the 3 injections regardless of the results of the subsequent Dick test; children receiving only 1 or 2 injections have been classified as non-immunized. Thus the data here presented measure the protection that is conferred upon a group of known susceptible children by the 3 injections of formalized toxin.

In all cases the control group has been calculated on the basis of the difference between the known tested group and the census population at that age.

It has been assumed that the same proportion of this residual group is susceptible to scarlet fever as was found in the group tested. That the group tested was a representative sample of the population is shown by comparable measles attack rates among the tested and residual non-tested group. It is realized that this means of estimating the control group is subject to a considerable hazard of errors, but it presented the only available method in view of our obvious inability to test but leave unimmunized a large control group.

IMMUNITY AS MEASURED BY SUBSEQUENT DICK TESTS

All of the children to whom formalized toxin was administered had been found to be susceptible as determined by a previous Dick test, usually performed the day before the first dose of antigen was given. Subsequent Dick tests thus measure the ability of the solution to render Dick negative a person known to have been previously Dick positive.

The early institutional data of Veldee as observed by us in Massachusetts indicated that over 80 per cent of those injected were rendered Dick negative. Subsequent studies in communities failed to bear out these early institutional findings, nor were the later results in institutions as favorable. The early observations in East Bridgewater and Wellesley were based on retests 2 to 3 months after the last injection. The first retest in Worcester was somewhat variable as to individual schools but averaged about 9 months after the last injection. The remainder, except for Bridgewater, which is discussed below, were performed 10-13 months after the last injection. Data are still lacking as to the most significant time interval at which to make these tests. As will be observed from Table I the retests show that approximately 50 per cent

TABLE I

All children Dick positive before being given formalinized toxin.

of those injected have been rendered Dick negative. Anything more exact than this generalization would be unwarranted as the variations between communities and within the same community have been too great, ranging from 21 per cent to over 60 per cent. The low figures of Bridgewater (30 per cent) are of special significance as they represent a deliberate attempt to test the immunizing effect of the formalinized toxin in the presence of minimum exposure to streptococci. This community of 10,000 population was selected as it had been free of recognized scarlet fever during the previous winter and thus represented a group in which the incidence of streptococci was supposedly at a minimum. The group was tested and immunization started June 7, 1935; it was retested October 30 of that same year during which time there was no known scarlet fever in the community. Thus the figures are based on observations during the season of minimum scarlet fever in a community with minimum infection. The low percentage of children rendered Dick negative (30 per cent) probably represents as nearly as possible the true immunizing effect of the antigen in the absence of reinforcement from exposure to hemolytic streptococci. It is not clear what may be the other factors in determining the level of protection established in a community.

Retest of a small group of children given a second course of injections

after being found Dick positive subsequent to the first series of injections showed that over 90 per cent of these children were rendered Dick negative. The figures are too small to be significant, but raise a reasonable question as to the added protection which might accrue from further injections of formalinized toxin.

PREVENTION OF SCARLET FEVER

The ultimate test of the value of the formalinized toxin depends upon its efficacy in the prevention of scarlet fever. As there is no readily applicable laboratory test upon which one may depend for diagnosis, reliance must be placed solely upon clinical interpretation, even though it is recognized that this is attended with many errors. As the same basis was used for diagnosis of both immunized and non-immunized groups this error is largely eliminated except for the possibility that the local physicians who believed in the value of the antigen might have been reluctant to make a diagnosis of scarlet fever in an immunized child and *vice versa*. Such a possibility can be neither denied nor affirmed though it is our belief that there has been no such weighting of the data in favor of the immunized group.

As an attempt has been made to reduce all observations to the basis of child-months of exposure at the different age limits, all rates have been calculated on the basis of 1,000 child-months of exposure. The small number of cases of scarlet fever that have occurred at each age level in any community introduces rather high variability to the age specific rates. Table II presents a sample of such rates for one community, Greenfield. It is, however, of significance that of a total of 73 possible comparisons in age specific rates that could be made in all the communities included in this study, 62 showed a lower rate among the im-

munized group. No comparison has been made if no case occurred in either group. Had there been no immunizing effect from this antigen there would have been approximately only 37 comparisons in which the rates would have been lower in the immunized groups. Some significance can be attached to such a sum of many observations, no one of which is of itself significant.

More valuable data can be obtained from summation of the data of individual communities. In doing so it has seemed fairer to treat the data for Worcester separately as in this community there was a different basis for selection of children to be immunized and the scarlet fever rate throughout the study was markedly in excess of that for the other communities. Were the Worcester data to be listed with the others, the major portion of the control group would have been composed of these Worcester children exposed to greater risk than the remainder, whereas, owing to the limitation of immunization to the parochial schools, the number of immunized chil-

dren for Worcester would have been but a very small fraction of the total. Thus the control group would have been unduly weighted with children subject to greater exposure and not strictly comparable with the immunized group. Summation of the remaining data has appeared reasonable as the scarlet fever rates in these several communities have not been too dissimilar and the proportion of the total child population immunized has been fairly comparable. All data included have been from the initiation of the studies in the several communities until July 1, 1937.

Table III shows all summarized observations in the grouped communities and the rates in the immunized and non-immunized groups.

Study of the incidence of scarlet fever cases in these communities may also be made through analysis of the hypothesis that the immunization program had no effect upon the incidence of the disease. This, indeed, is the basic hypothesis which should always be factually repudiated before its alternatives merit consideration. If the im-

munizing program had been without effect on the incidence of scarlet fever in the communities under consideration, then the incidence rate for each age class may be secured from the recorded cases and computed child-months of exposure. These age specific rates may then be applied to the child-months of exposure for the immunized group to compute the expected number of cases in that group assuming no effect of the immunizing program. From Table IV

it will be seen that but 43 cases occurred as compared with an expected total of 71. It is thus apparent that although there were failures of immunization, there was a distinct reduction in the incidence of scarlet fever in the immunized group.

The data for Worcester are analyzed separately in Tables V to VII. In this city (190,000 population) the immunized group (parochial school children) may be compared with either the

non-immunized parochial school group or with the public school group. Comparison of attack rates shows significantly lower rates among the immunized than among either control group. By comparing the number of cases that occurred in the immunized group with the expected number of cases as calculated from the total community incidence (Table VI) it will be seen that there were but 5 instead of the expected 45. The comparison between the cases among the immunized and the expected number based on the rate for the entire parochial school system is also significant. Whether or not the lower rate of scarlet fever in the parochial schools be due to less adequate diagnosis or reporting, or to an actual reduction attributable to immunization of about one-third of the susceptibles (see below) is a matter that cannot be answered as yet, though there is evidence to suggest the latter. The comparison with the expected number of cases as determined by the rate in the parochial schools is therefore of greater significance than is the other comparison, as the groups are certainly comparable with respect to diagnosis and reporting. This comparison shows but 4* cases instead of the expected 21 (Table VII).

FAILURES OF IMMUNIZATION

As may be observed from the tables there have been 48 children in the communities studied who have been reported as having scarlet fever at some time after the 3 injections of formalinized toxin. Three of these were children who had been tested after im-

munization and found to be still Dick positive but received no further injections. Another had been given a second course of antigen, and one developed scarlet fever a few months after an apparently negative test following immunization. The remainder had not been tested between the date of the last injection and the occurrence of the scarlet fever.

Of this latter group it has been possible to retest 10 children some few months after the scarlet fever. Eight of these were found to be still Dick positive. Several explanations may be advanced to explain these findings— infection due to a different strain of streptococci, error of diagnosis, or the existence of a group of individuals incapable of developing antibodies.

DURATION OF IMMUNITY

It is impossible at present to advance any significant data as to the duration of immunity induced by formalinized toxin. The community studies have been carried on for too short a time, and too few of those originally immunized have reappeared for testing to yield data of value. Institutional data, which have not been included in this report show, however, no significant tendency to relapse to a Dick positive reaction.

REACTIONS

Reactions following the administration of the formalinized toxin have been so mild that there has been as hearty acceptance of this immunizing procedure as has been accorded to diphtheria immunization in the same communities. This is especially significant as no attempt has been made to urge its acceptance and no promises made as to its effectiveness. The opinion of the school teachers who have observed its use in the schools has quite uniformly been that it produced no more severe reactions than followed diph-

* Although the Worcester program attempted to reach only the parochial school children, a few younger brothers and sisters of preschool age were brought to the clinics for immunization. One 3 year old immunized child developed scarlet fever. As there was no control group of this age within the parochial schools, this case has been omitted in this comparison though included with that based on the entire city.

theria toxoid administration. Our personal observations in both institutional and community-wide programs would bear out this opinion except for a somewhat more extensive area of erythema which was, however, devoid of tenderness. Subjective symptoms are rarely encountered.

In order to obtain more objective data as to the reactions following the administration of this antigen, studies have been made of the maximum temperatures observed routinely in tuberculous children at the time of such injection. From Table VIII it will be observed that there was but a slight increase in febrile reactions. Thus of 2,250 observations the number with a normal temperature after injection fell to but 53 per cent as compared with 64 per cent before injection. The percentage with less than 1° rise increased from 33 per cent to 39 per cent, and those with more than 1° rise increased from 2.5 per cent to 7.5 per cent. Thus when we compare the population showing a febrile reaction after immunization with those showing such temperatures during the 2 days preceding the injection (rather than attributing to the antigen all subsequent disturbances) we find that there was barely 10 per cent increase of febrile disturbances which might be attributed to the injection.

Subjective symptoms are more difficult to evaluate. Studies made of school attendance before and after immunization showed no increase in absences even in those groups where as many as 50 per cent of a class were treated. A similar measure of subjective symptoms may be obtained through studies of the percentage of those children who did not complete a course of immunization upon which they had embarked. From Table IX it will be seen that only 11 per cent of those that began the treatments failed to complete the full course. These figures are comparable to those for diphtheria toxoid clinics in Massachusetts in which from 10 to 20 per cent fail to take the complete course of 3 doses. Thus it is apparent that the formalinized toxin produces reactions which are not essentially different in severity from those encountered following the administration of diphtheria toxoid.

TABLE IX
Percentage of Children Completing Immunization

Dick Tested	14,337
Dick Positive	9,475
No injections	202
Started course of injections	9,273
Three injections	8,212 (89%)
Two injections only	569 (6%)
One injection only	445 (5%)

CONTROL OF SCARLET FEVER

It would be hazardous to venture any claims as to the effect of the community program in controlling scarlet fever. The findings presented below, although suggestive of some such effect, may be accidental observations which would be reversed over a longer period of time. The data are therefore presented merely for the completeness of the record.

Table X shows the scarlet fever morbidity rates in those communities in which such programs were conducted. The year in which the immunization began is marked with an asterisk. It must be remembered, however, that in most instances the work was not initiated until toward the end of the spring and in some cases not until the fall. Thus the rate during the initial year would not be affected by the program. Cities in which the work did not begin until late in 1936 and the southern Berkshire area, data for which have not been included above, are omitted. It will be noted from the table that except in Worcester where less than 3 per cent of the child population was

immunized there was a quite uniformly lower rate during the post-immunization years than prior. It should be added, however, that the years 1935 and 1936 were years of low incidence of scarlet fever for the state as a whole, though in certain sections the disease was abnormally prevalent.

A better comparison of the incidence of scarlet fever in the immunized and non-immunized communities may be obtained from a study of groups of communities. Such data are included in Table XI. It will be noted that Natick, which lies directly between Wellesley and Framingham and was not immunized (in spite of repeated requests for this service), experienced an unusually high rate of scarlet fever during the same time that its two adjoining communities were unusually free of the disease. A similar phenomenon is apparent in the comparison of Beverly and Gloucester, each a city of about 25,000 population and separated by about 15 miles. Gloucester was selected for immunization because it seemed apparent it should experience a high incidence due to spread

† Not immunized

from Beverly and the adjoining cities of Peabody and Salem where the disease was unusually prevalent. That after immunization of about one-third of the school children the disease should decline rather than increase may have been due either to chance or to some partial immunizing effect. Similar conclusions hold for Westfield and Greenfield. It had been hoped that immunization work might be carried on in Westfield beginning in April, 1935, as the high incidence of the disease in surrounding communities suggested an early increase in Westfield. The work was not undertaken, however, owing to the refusal of the local board of health to permit such a program. Consequently, the program was initiated in Greenfield, some 50 miles north in the Connecticut Valley. The table shows that scarlet fever which was increasing rapidly throughout the valley did invade Westfield as expected but failed to do so in Greenfield. The data for the first half of 1937 show a continued striking difference between these two communities.

DISCUSSION

From the foregoing preliminary data it is apparent that the formalinized

toxin used in this study has an appreciable immunizing value as measured both by Dick tests and by protection against clinically recognizable scarlet fever. This immunizing effect is not as great as that due to the use of standard 5 injections of Dick toxin which will render Dick negative about 90-95 per cent of those previously susceptible, as shown by the work of numerous investigators. The clinical data for the use of the two antigens are not strictly comparable. The use of the formalinized toxin is, however, attended with so few reactions that it has been accorded a really popular acceptance in all groups to which it has been offered, even though no attempt has been made to persuade the parents to consent to its use. Subsequent programs in the same communities have shown no loss of popular acceptance.

These considerations raise a serious question as to the possible place which such an antigen might occupy as a means of reducing the incidence of scarlet fever on a community-wide basis. The Dick immunizing toxin has not been accorded the popular acceptance which it deserves when judged solely on the basis of its effectiveness. This lack of acceptance is due basically to

the relative severity of the reactions attendant upon its use, which, during the present era of mild scarlet fever, often appear to the public to be little preferable to the disease itself. Thus the Dick toxin, though giving a satisfactory protection to a very high proportion of those to whom it is administered, has failed to reach a sufficient fraction of the susceptible child population. In our experience the formalinized toxin will reach so large a group that, even though a less powerful antigen, its widespread use will result in the protection of an appreciable fraction of the susceptible group. It is unfortunate that administrative considerations should at times supersede scientific values, but practical experience shows that the community value of an immunizing procedure is no greater than the popular acceptance accorded to it. The history of smallpox vaccination has long offered ample proof of this statement, and the history of Dick toxin immunization has, unfortunately, offered further substantiation of it.

Whether or not the community immunizing value of such a solution is measurably greater than would be suggested by the above data is a point that must await further elucidation. Theoretical considerations lead one to the conclusion that immunization of a reasonable fraction of a susceptible population confers an effective herd immunity upon that community. The studies of Godfrey bear out this theory with respect to diphtheria. Observations are still lacking with respect to scarlet fever but our data have at least suggested a community protection greater than might

be expected from the results of the skin tests. Whether or not some of this protection is due to the existence of an effective clinical immunity of a higher level than is shown by tests is a matter which must await further study, though certain data not here included could be advanced in support of such a contention.

It would appear, therefore, that a formalinized toxin solution, though a less powerful antigen than the Dick toxin, might well serve a useful purpose in community-wide programs for the control of scarlet fever. It is far from an ideal antigen but possesses certain advantages which compensate in part for its deficiencies. There is great need for further studies as to improved antigens or improved methods of administration of existing antigens. The studies described above in preliminary form are being continued together with other studies along the lines herein suggested.

CONCLUSIONS

1. Formalinized toxin solution administered as herein described is a less potent immunizing agent than is Dick toxin.
2. About 50 per cent of those susceptibles treated with formalinized toxin are rendered Dick negative, though this figure varies widely in different groups.
3. Control skin tests are essential in the interpretation of Dick tests on persons immunized with formalinized toxin.
4. The incidence of scarlet fever among children given 3 doses of formalinized toxin is substantially lower than in those not so protected.
5. The reactions following the injections were no more severe than those due to diphtheria toxoid.
6. Immunization with formalinized toxin is as readily accepted by the public as is diphtheria immunization.

Result of Active Immunization of Nurses Against Scarlet Fever*

EDWIN H. PLACE, M.D.

Boston City Hospital, Boston, Mass.

ACTIVE immunization against scarlet fever with large doses of toxin has been found universally to render a high proportion of persons negative to the Dick test. Occasional attacks of scarlet fever due to heterologous strains may occur in persons negative to tests with the standard toxin. There is apparently a lack of specificity of the hemolytic streptococci causing various clinical forms of infection in humans. Whether the standard toxin will protect immunized persons against most clinical attacks of scarlet fever, and especially whether such immunized persons are protected against infection or only against the toxin, can be determined only by collected experiences under actual conditions of exposure.

The present report is based on observations of the nurses in the South Department, Boston City Hospital for the past 24 years.

A small group of nurses was immunized by Branch and Edwards early in 1924. Since 1925, the majority of the nurses have been immunized actively against scarlet fever. The Boston City Hospital nurses have been immunized chiefly in the probationary period by the standard method in the Department of Immunology and are assigned to the scarlet fever wards within

1 to 2 years. Sixty-five per cent of the nurses come from other training schools in Maine, New Hampshire, Vermont, and Massachusetts. Immunizing practice has not been universally good or standard throughout this time in some of these schools.

For the 12 years, 1913-1924, of 1,009 nurses in training 87, or 8.6 per cent, developed scarlet fever. In the following 12 years, 1925-1936, of 1,446 nurses serving in the wards, 20, or 1.3 per cent, contracted scarlet fever, a reduction to 15 per cent of the former rate. Of these 20 nurses, 13 had not been immunized, 3 had had only 500-875 units of toxin, $4\frac{1}{2}$ years, 1 year, and 10 days, respectively, before scarlet fever onset, 1 had received Lilly's Antigen (Larsen) 8 months before scarlet fever, and only 3 had received the complete series of toxin injections. If the completely immunized only were considered in this group the incidence would be 0.21 per cent, a reduction to 0.24 per cent of the former rate.

Of the 3 immunized nurses who developed scarlet fever, 1 never became negative after two series of injections, and the other 2 were not tested after immunization. Two of the 3 had positive Dick tests, 1 before and 1 at the onset of scarlet fever, and 1 was not tested. Only 3 of the 20 cases of scarlet fever were in the Boston City Hospital training school, 2 of which had been immunized with small doses

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

CHART I—Scarlet fever incidence in South Department, Boston City Hospital, nurses per 1,000

and 1 had had a previously negative Dick test a few months before scarlet fever.

Of the 13 non-immunized nurses who developed scarlet fever in the second period, 5 had never been Dick tested, 3 of whom were positive just before or at the attack and 2 negative early in the attack. Three of the 13 had had positive tests but had not been immunized. In 1 the result of the test was not obtainable and 4 had been negative. Of these 4 negative, 2 had positive Dick tests at the South Department and 2 were not tested here. One was reported negative although the nurse noted redness the size of a dime 10 hours later which had faded in 24 hours.

This drop from 8.6 per cent to 1.3 per cent in incidence was not associated with a corresponding decrease of scarlet fever in nurses in general in this region.

One hundred twenty-seven nurses were admitted with scarlet fever in 1913-1924 from hospitals having no contagious services, and in the next 12 years 100 nurses were admitted. Immunization in the hospitals supplying these patients either had not been generally done or had been done only during the last 3-4 years. Forty nurses were admitted from the Boston City Hospital (Proper) in the first (non-immunization) period and 35 in the second period.

The degree of exposure of the nurses in hospital service is subject to great variation and cannot be accurately estimated. The total number of scarlet fever admissions to the hospital and the incidence of scarlet fever in Boston during these 24 years has actually been higher during the period of immunization (Chart I).

In 1922, the training course was re-

duced from 6 months to 3 months. The average time of assignment to the scarlet fever wards in the first period was 41.5 days and in the second period 31.3 days. The difference is actually less significant than this. For example, in the first period 28 per cent of the nurses were assigned to scarlet fever wards for 50 days or more for a total of 50 per cent of the whole nursing time. In the second period, there was much less variation, as only 1.3 per cent served in the scarlet fever wards for 50 days or more for a total of 2 per cent of the whole nursing time of this period. Also, since 1922, nursing contact with scarlet fever occurs more or less constantly

on the isolation wards in addition to scarlet fever wards. An analysis of these conditions fails to indicate any significant factor for the reduction in scarlet fever other than the toxin immunization.

But is the disease occurring unrecognized because of the abolishment of the rash? This is not so easily determined. In the 12 years before immunization, admissions of nurses with streptococcal infections other than scarlet fever occurred in 65, or 6.4 per cent, and since immunization in 67, or 4.6 per cent.

The total loss of time due to all illnesses during the first period was 11.3 days average for each nurse and during

1935	148	3	20.2	543	232.8
1936	141	1	7	762	304.4
Total	1,446	20	13.8		

CHART II—Nurses from general hospitals admitted with scarlet fever compared with incidence in nurses in contagious hospital

the second period 4.8 days. Diphtheria immunization, begun in 1918, accounts for some of this reduction, but comparing 1920-1924 and 1925-1929, shows an average of 7.3 days illness per nurse in the former to 4.2 days for the latter period.

Prevalence of scarlet fever in nurses in the probationary period, before immunization has become fully effective, has shown no increase through contact with nurses who have served in the scarlet fever wards; and the occurrence of scarlet fever in the pediatric wards and in the diphtheria, measles, and whooping cough wards has decreased since immunization.

It is difficult to estimate the number of nurses contracting scarlet fever recognized only because of the rash, who would not even report illness if the rash were not present. From a series of

cases it does not seem probable that it would be as high as 10 per cent.

RÉSUMÉ

The incidence of scarlet fever in nurses in contact with scarlet fever in the South Department, Boston City Hospital, was 86.2 per 1,000 before immunization and 13.8 per 1,000 after immunization comparing 12 year periods. Only 3 of the 20 nurses developing scarlet fever since immunization had had the complete series of immunizing injections. Two of these had not been retested after immunization and one had remained positive after 2 series of injections.

One hundred and twenty-seven nurses were admitted in the first period (1913-1924) with scarlet fever from hospitals not supposed to accept scarlet fever, and 100 such nurses were ad-

A = Nurses from affiliated schools

mitted 1925-1936. In recent years many of these hospitals have begun immunization.

The conditions of contact of nurses with scarlet fever are obviously greatly variable but no significant difference could be made out to account for the striking reduction of prevalence.

The incidence of streptococcal infections such as tonsillitis, septic sore

throat, erysipelas, and peritonitis (aside from scarlet fever) was 64.4 per 1,000 in the first period, and 46.6 in the period of immunization.

The total loss of time from all illnesses was 11.3 days average in the first period and 4.8 days in the second.

The prevalence of scarlet fever in the children in the pediatric, measles, whooping cough, and diphtheria wards

CHART III—Cases of scarlet fever admitted to South Department, Boston City Hospital, and scarlet fever incidence per 10,000 in Boston

has shown no increase since immunization of nurses.

CONCLUSION

Toxin immunization of nurses carefully done largely abolishes the evidence of scarlet fever during their contagious disease training. There is no evidence that the disease is still occurring in unrecognized form.

Sanitary Aspects of Air Conditioning*

C. P. YAGLOU

Assistant Professor of Industrial Hygiene, Harvard School of Public Health, Boston, Mass.

THIS paper summarizes the comfort, health, and therapeutic aspects of air conditioning in the light of present knowledge and current research.

In the evaluation of these aspects, it is desirable to distinguish between winter and summer air conditioning, since the requirements and the effects of air conditions differ considerably in the two seasons. According to engineering terminology, the functions of winter air conditioning are heating, humidification, air circulation, and filtration; those of summer air conditioning are cooling, dehumidification, circulation, and filtration. These definitions are purely arbitrary in that they do not distinguish between important and unimportant functions.

WINTER AIR CONDITIONING

From the standpoint of comfort and health the problem of winter air conditioning appears to be mainly one of rational heating supplemented with adequate building insulation and with sufficient ventilation, by natural or mechanical means, to remove objectionable body or tobacco smoke odors.

Air and Wall Temperatures—Air temperature and particularly sharp temperature changes are as a rule the most important factors. While a mod-

erate variability of temperature toward the cooler side of the comfort zone is stimulating and probably beneficial, there is much good evidence to show that great temperature changes may have a deleterious influence by increasing susceptibility to upper respiratory diseases. A most difficult problem in winter air conditioning is how to reduce the sudden temperature changes experienced in passing from a warm room to cold outdoor air. Obviously, this is difficult to accomplish with conventional methods and equipment. Some persons believe that the solution of the problem might be found in radiant methods of heating, but so far nothing practical has been achieved.

Next to air temperature, the temperature of the exposed walls and glass is of considerable importance. A room heated by the usual convectional methods may be uncomfortably cool at 75° or even at 80° in cold weather if the insulation of the walls is poor. Owing to a steep temperature gradient between floor and ceiling, the feet are cold and the head is too warm, a condition that is inimical to comfort and health.

Years of experience in England have shown that a combination of warm walls and relatively cool air is distinctly more comfortable and pleasant than one of cold walls and warm air; such an arrangement also reduces to some extent the temperature contrasts between

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

outdoors and indoors. Radiant panel heating methods have distinct advantages in these respects, but their applicability to cold climates involves a number of economic and engineering difficulties that have yet to be overcome. Work now in progress at the John B. Pierce Laboratory of Hygiene, under the direction of Dr. Winslow, may shed considerable light on disputed points.

Suitable wall insulation, in conjunction with convectional heating methods, will materially improve the comfort of a room by reducing infiltration and by keeping the inside surface temperature of the exposed walls close to the air temperature. Such a room would be comfortable at temperatures between 70° and 73° instead of 75° and 80°, in poorly constructed buildings.

Aside from comfort, insulation has important economic aspects. It allows a reduction in the size of the entire heating plant and effects a substantial saving in fuel consumption by reducing structural heat losses and by permitting a lower room temperature.

Humidity—This factor, although very important in warm weather, is of little consequence in cold weather except in special instances. The usual variations of humidity during the heating season have been found to produce little effect on comfort, and from the standpoint of health the evidence is overwhelmingly on the negative side. Subjectively, a low humidity is generally preferred to a high one, especially when the latter is obtained by mechanical methods. Exceptions have been found in persons suffering from frontal sinusitis and other infections of the upper respiratory tract characterized by excessive dryness of the nose. The same subjects, however, disliked the humid air after their condition improved.¹ A low humidity also seems more agreeable than a high one in catarrhal conditions of the nose² but

the data are too meager to allow a definite conclusion. In the light of these suggestive data, a study of the effects of dry and humid atmospheres on upper respiratory disorders may offer a fruitful field for research.

In properly heated buildings, the natural relative humidity seldom falls below 20 per cent owing to a stabilizing influence of hygroscopic materials in the walls, furniture, etc. Artificial humidification may lead to serious trouble from condensation and freezing of the moisture inside certain building materials composing the outside walls. Even in buildings constructed of waterproof materials, relative humidities above 40 per cent are troublesome in cold weather.

Air Movement and Drafts—Within the usual limits, air movement is not a factor of great importance. The aim in ordinary ventilation work is to keep the movement of air at or slightly above the threshold of perceptibility so as to impart a sense of freshness without drafts. Usual practical values are between 15 and 50 f.p.m. during the heating season.

The problem of drafts is difficult to solve to the satisfaction of all because the trouble does not always arise from faulty air conditions but often from an inherent instability of the heat-regulating system of the body, particularly from poor blood circulation to the extremities and deficient vasomotor response in certain individuals. The draft-susceptibles may suffer considerably on exposure to ordinary air conditions that are perfectly satisfactory to the majority of normal persons. Even a temperature of 72° with an air movement of 20 f.p.m. may prove objectionable to some persons who like heat and cannot stand the cold, because of their low metabolic rate. Such individual idiosyncrasies may be counteracted by the use of suitable clothing that will keep the extremities warm.

Few persons, however, would be willing to depart from custom and fashion unless their health is seriously threatened.

Mechanical Ventilation and Air Cleaning—These two factors are very important in theatres, auditoriums, industrial plants, etc., where large volumes of air must be constantly supplied, but in the average home and uncrowded office natural ventilation is sufficient for every practical need, except in the kitchen and bathroom where separate means of ventilation are desirable in order to prevent diffusion of odors to other sections of the building.

According to prevailing belief, the minimum fresh air supply in general ventilation work is that needed to dilute and remove unpleasant body or other odors that have hygienic significance. In experimental work the amount of outside air needed for the removal of body odors was found to vary from 5 to 38 c.f.m. per person, depending largely on the cleanliness of the occupants, the air space per person, and the type of air-conditioning apparatus.³ Under ordinary conditions, a fresh air supply of about 15 c.f.m. per person appears to be quite satisfactory in public buildings when each occupant is allowed an air space of about 200 c.f.m. This quantity is usually sufficient to satisfy the thermal requirements, except in warm weather when the air is not cooled artificially. In all instances, the total air supply, including outside air and recirculated air, must be sufficient to maintain comfortable thermal conditions and to prevent the accumulation of objectionable odors.

In industries where the primary object may be the control of toxic dusts, fumes, or gases, the air supply must be sufficient to dilute the polluting elements to a concentration below the physiological threshold.

So far as ordinary atmospheric dust is concerned, the objection is believed

to be not so much a matter of health as of nuisance and esthetics.⁴

Health and Economic Aspects of Winter Air Conditioning—In the past few years, several studies have been carried out to determine whether winter air conditioning affects favorably the health and efficiency of office workers. The best controlled studies were those of McConnell⁵ at the Metropolitan Life Insurance Company, including a total of 10,000 employees, half working in conditioned offices and the other half in offices not equipped with air-conditioning equipment but otherwise properly heated and ventilated. Records of illness, absenteeism, and other pertinent factors showed no significant difference between the two.

Reports from commercial sources are quite contradictory. Claims are often made of definite benefits to health and efficiency, but the data are too meager and without controls. Such data are probably of little value owing to the well known variability in the incidence of upper respiratory diseases from year to year and month to month.

We must admit at the outset that the evaluation of any specific influence on health is extremely difficult, because of lack of suitable standards and the simultaneous operation of many extraneous factors outside the place of work, some of which have probably a much more powerful influence than the air conditions at work. All we can say at present is that no authentic evidence exists to prove any superiority of winter air conditioning over rational heating in homes and public buildings.

SUMMER AIR CONDITIONING

Cooling in warm weather may contribute much to the comfort or discomfort of man depending upon the method and extent of cooling. Much has yet to be learned about this important branch of air conditioning. Above all, temperature contrasts must not be too

great. An indoor temperature even 10 to 15° F. below the outside temperature, as is now the practice in warm weather, appears to be objectionable and harmful to some persons. We often hear of head colds originating in over-cooled theatres, restaurants, or railroad cars on warm summer days. Headaches, stomach upsets, and a general feeling of fatigue are other conditions attributed to overcooling. Although many healthy individuals seem to be perfectly capable of adjusting themselves to such temperature changes, without discomfort or after-effects, little is known about possible damage to health that may result from too frequent exposure.

Adaptation to summer heat renders the organism sensitive to cold and temperature changes, especially when the body surfaces are wet with perspiration. The tone of the heat producing organs is depressed and the metabolic rate may fail to increase sufficiently, or quickly enough, on exposure to sudden chilling.⁶ The "cold shock" experienced on entering a cooled space on a warm day is found to be due to an excessive increase in the heat loss by evaporation of perspiration without an immediate compensatory increase in the metabolic rate.⁷ Conversely, the feeling of depression and discomfort experienced in passing from a cooled space to warm outdoor air appears to be due to a lag in sweat-gland activity and the consequent retention of body heat.

The solution of the problem would seem to lie in dehydrating the air to a comparatively low humidity, without reducing the temperature more than a few degrees below the prevailing outdoor temperature. In this way, temperature contrasts are moderated upon entering and leaving the conditioned space and, according to current research, there are no untoward symptoms in the transitional period of readjustment.

Health and Economic Aspects of Summer Air Conditioning—The benefits of summer cooling in commercial and industrial fields are now generally appreciated. There is much good evidence to show that cooling under adverse conditions of heavy physical work and heat should prove beneficial to both employer and employee by increasing the output, decreasing illness and accidents, and lessening fatigue.⁸ In office work, however, where the physical activity is light, McConnell⁹ was unable to detect any significant improvement in the health or efficiency of approximately 6,000 employees of the Metropolitan Life Insurance Company in the course of a summer season, despite the conspicuous improvement in comfort. The employees were able to pursue their work without the depression and discomfort experienced prior to the installation of cooling apparatus.

For the average home and small office, cooling may be a potential necessity, but for the time being, it is still too expensive for general use. In many sections of the country where the nights are usually cool, suitable building insulation, including the use of awnings, and the circulation of cool night air will generally afford sufficient relief during the heat of the day.

THERAPEUTIC ASPECTS OF AIR CONDITIONING

Aside from comfort and health, air conditioning is proving to be a valuable adjunct in the treatment of disease.¹⁰ In operating rooms, conditioned air is gradually becoming indispensable in reducing the risk of explosion of anesthetic gases and safeguarding the patient, surgeon, and operating team against excessive summer heat.

In premature nurseries of institutions, the maintenance of a suitable temperature, according to individual requirements, with a relative humidity

of about 65 per cent, as determined by extensive research, results in a great reduction in the incidence of respiratory and gastrointestinal diseases, and improvement in the infants' chances for life.

In the artificial production of therapeutic fever, conditioned air is proving to be the preferred method of treatment. In oxygen therapy, air conditioning is concerned with the conservation of oxygen, and the removal of excess carbon dioxide, heat, and moisture.

Hay fevers and pollen asthma offer a wide field for application of air conditioning in the home, office, or clinic, the main objective being adequate filtration of air. Unlike specific desensitization, treatment by conditioned air is not curative but gives only temporary relief. With rare exceptions, the symptoms recur on exposure to pollen-laden air.

Cooling in warm weather is of great assistance in the treatment of pyrexias of the new-born, in enteric disorders, fevers, heat stroke, heart failure, and a variety of other ailments that often accompany summer heat waves. Considerable research is now in progress on a wide variety of diseases in which

air conditioning may prove of value.

Of particular significance to operating rooms and contagious wards is the recent use of ultra-violet light for sterilizing air. This phase of air conditioning will be separately discussed by Mr. Wells¹¹ and need not, therefore, be taken up here.

Standard Agar Counts as Compared With Counts on Improved Agars at 32° C.*†

M. W. YALE, PH.D.

Department of Bacteriology, New York State Agricultural Experiment Station, Geneva, N. Y.

THE American Public Health Association has under consideration an improved plating medium and an improved incubation temperature for official use in the bacteriological examination of dairy products. The improved agar which has received most study is a tryptone-glucose-skim milk medium, developed by Bowers and Hucker¹ in 1935. This medium contains 0.5 per cent tryptone (hydrolyzed casein), 0.1 per cent glucose, 0.5 per cent skim milk and 1.5 per cent agar.

At the request of the Committee on Standard Methods for the Examination of Dairy and Food Products, Difco Laboratories, Inc., prepared dehydrated media according to the above formula both with and without milk, and sent trial packages of one or both to 91 laboratories for comparisons with standard nutrient agar. The types of laboratories receiving tryptone media were as follows: milk or ice cream companies, 39; commercial, 5; health and control, 24; and educational institutions, 23. Seven were in foreign countries (England, Denmark, Germany, Syria, Cuba, and Hawaii).

Dr. R. S. Breed, Chairman of the

Standard Methods Committee, asked the author to summarize the data. This summary (Table I) includes 42 reports by 56 laboratories on 23,715 samples of dairy products.

The majority of the laboratories received a tryptone-glucose medium and added 5 ml. of good quality skim milk per liter prior to sterilization. A few laboratories failed to add the milk, but since several studies have shown only a slight increase in count due to the addition of this amount of milk, no distinction is made in Table I between tryptone-glucose and tryptone-glucose-skim milk agar.

Only 14 of the 42 reports have previously been published.¹⁻¹⁴ Of the 28 unpublished reports, 15 were from health or other control laboratories, 7 from laboratories in educational institutions, and 6 from industrial or commercial laboratories. About 50 per cent of the work was done using incubation temperatures of both 37° C. and 32° C. for 48 hours, the latter being one of the improved incubation temperatures under consideration for official use in the examination of dairy products. Some laboratories did not use the lower temperature because 32° C. incubators were not available.

It is not within the scope of this paper to discuss still other modifications used by 15 of the laboratories as indi-

cated in the right hand column of Table I. Safford and Stark,³ Eglinton, Stone, Perry, Hohl, Brown, and Difco Laboratories tried several improved agars which yielded on the average higher counts than the tryptone agar described in this paper. Some of these modifications show possibilities of an even greater improvement over standard agar than does the formula used in the present research work and merit further consideration.

RESULTS OBTAINED

On the tryptone medium, colonies were larger than on standard agar and easier to count both because of their size and because of the opaqueness of the medium due to the added milk.^{1, 2, 4, 5, 6, 7}

Frayer,⁶ in a study of about 4,000 plate counts made by several technicians on 18 samples, found that counts on replicate tryptone agar plates incubated at 32° C. were less variable than counts on replicate standard agar plates incubated at 37° C.

This is an important point in favor of the modified method since its use would result in greater uniformity in results obtained by different laboratories. The increased accuracy of counting is presumably due to the greater ease with which colonies can be counted on the tryptone medium.

Bowers and Hucker¹ found that mastitis streptococci grew better on the tryptone medium than on standard agar where they grew either as "pinpoint" colonies or not at all. Other studies have shown that these organisms grow equally well at 32° and 37° C.

Yale and Pederson¹⁴ reported that thermophilic bacteria, occasionally present in large numbers in pasteurized milk, do not grow well at either 32° or 37° C. and that a higher incubation temperature than 37° C. is necessary for their best development on agar plates.

Bradfield⁵ discovered that certain types of contamination had a definite relationship to increases in counts developed by modified plating methods. Organisms arising chiefly in the udder responded to the standard agar and 37° C. incubation temperature almost as well as to the modified methods. Types carried into the milk by utensils developed better at the lower incubation temperature and with the modified medium than with the standard procedure. Those derived from feed, bedding, or stable dust developed better at the lower temperature than at 37° C., but there was no advantage for either the modified medium or temperature when the source of contamination was fecal or dermal. Types predominating in improperly cooled milk developed greatly increased counts on the modified medium, particularly when incubated at 32° C.

If it is desirable to use a procedure which will grow bacteria associated with unclean utensils and inadequate cooling, a modified medium and temperature are clearly advantageous.

EFFECT OF MODIFIED METHODS ON COLONY COUNTS

Bowers and Hucker¹ showed in their original work using the modified medium at 37° C. that the average increase in count was greater in pasteurized milk than in raw milk. The majority of reports confirm this finding. Phelan⁸ studied samples collected throughout New England and examined in the laboratories of the Hood Company at Boston. He used the modified medium at both 37° and 32° C. and found striking differences in increases in counts obtained in different classes of dairy products. The least increase occurred in certified raw milk, and the greatest in pasteurized cream where it exceeded 80,000 per cent in almost 1 per cent of the samples tested. Grade B raw milk yielded greater increases

than Grade A raw, and Grade B pasteurized yielded greater increases than Grade A pasteurized. These observations have been confirmed by other workers.

Stone found in the case of California samples that increases due to the modified medium were, on the average, about 30 per cent for raw milk and about 100 per cent for pasteurized milk. In California, increases in count using the modified medium at 37° C. are apparently less than in certain other sections of the country because their milk supplies have been so largely freed of those types of bacteria which fail to grow on standard agar at 37° C. Hardenbergh at Plainsboro, N. J., examined 280 samples of certified raw, and 30 samples of certified pasteurized milk, using a dilution of 1:100, and reported that standard agar counts were higher than tryptone agar counts in the majority of cases. Undoubtedly, the organisms present were almost entirely udder types which grow as well or better on standard nutrient agar than on the modified tryptone medium.

Several millions of dollars are annually paid to Grade A dairymen in this country as premiums for raw milk delivered with a low bacterial count. Yale studied data furnished by 3 New York City and 2 Philadelphia companies on 4,699 samples of Grade A raw milk. From the information obtained, equitable adjustments can be made so that neither producers nor dealers will suffer financial losses if changes are made in plating methods.

While the modified temperature exerts a greater effect on the count than does the modified medium in fluid milk, Curtis and Hileman¹⁰ found that the modified medium had the greater effect on the count in dry skim milk.

The modified incubation temperature is especially advantageous for use with ice cream due to the abundant presence of types with an optimum growth tem-

perature nearer 25° or 32° C. than 37° C. Robertson¹² summarized data furnished by 5 ice cream companies and compared the effect on the count produced by the modified medium and the modified temperature. He concluded that the modified temperature had the greater effect.

Data obtained by the various laboratories listed in Table I are in general agreement. The variety of ways in which results were reported made the preparation of a summary difficult and, for this reason, one outstanding study was selected for discussion rather than the work as a whole.

Kelly⁹ acted as collaborator for the International Association of Milk Dealers in summarizing data collected by 17 milk companies in 10 states. The study was carefully planned in advance and complete directions sent to each laboratory. Through the courtesy of Mr. Kelly and the International Association of Milk Dealers, the cards containing the original data on 4,248 samples of milk and cream were loaned to the author and a frequency distribution table prepared (Table II).

Table II shows the number and percentage of instances in which increases or decreases fall within a certain percentage increase or decrease range. The groupings correspond closely to those used by Bradfield⁵ with the exception that the group designated "no increase or decrease" is slightly broader, taking in minus 5 to plus 5 per cent.

Three points are brought out strikingly by the results shown in Table II. First, the numbers and percentages show that the modified temperature had a greater effect on the count than the modified medium while the combination had a greater effect than either alone. The average percentages of increase or decrease showing the effect of change in incubation temperature, the change in medium, and the combination of the two are +37, -7, and +59 per cent

* Standard nutrient agar.

† Original formula of Bowers and Hucker containing 5 gm. tryptone, 1 gm. of glucose, 5 ml. of skim milk and 15 gm. of agar per liter. The dehydrated tryptone-glucose medium was supplied by Difco Laboratories, Inc.

decrease of —7 per cent in the case of the raw milk samples and the modified medium is misleading since it was due to a single sample. If the one sample is omitted, an average increase of 56 per cent is obtained. This affords an excellent example of the limitations of arithmetical averages.

In the second place, the increase in count due to modified methods is least in raw milk and progressively greater in Grade A pasteurized milk, Grade B pasteurized milk, and greatest of all in pasteurized cream, as illustrated by average percentage increases in count on tryptone agar with 32° C. incubation of 59 per cent in raw milk, 120 per cent in Grade A pasteurized milk, 191 per cent in Grade B pasteurized milk, and 245 per cent in pasteurized cream.

The third important point is that the use of modified methods does not merely result in a constant percentage increase in count. Many persons have not realized this and have opposed change in methods on the ground that there is no advantage in change if it merely results in a constant increase in count. While analysis of data by arithmetical averages may tend to convey this impression, analysis by frequency distributions (Table II) shows wide distribution in the range of decreases and increases. This indicates that the average percentage increase in the case of the modified methods is relatively uncommon.

SUMMARY AND CONCLUSIONS

The study of about 24,000 samples of dairy products by 56 laboratories shows conclusively that modified methods produce a greater spread between counts of truly good quality and truly poor quality products than does the present standard method. The numerical increase in count is slight in the case of truly high quality products.

At the present time, there is considerable lack of confidence in standard agar plate counts and a trend away from their use. Adoption of a better standard medium and a lower incubation temperature should do much to restore confidence in colony counts because of the better correlation between results obtained by inspectors and laboratory workers than is the case at the present time.

NOTE: Grateful acknowledgment is made to the many persons who assisted in the collection of the data which made this report possible.

Syphilis Control in Industry*

R. R. SAYERS, M.D., F.A.P.H.A.

Senior Surgeon, Division of Industrial Hygiene, National Institute of Health, Washington, D. C.

AT the turn of the century we were ignorant of the essential problems in the control of syphilis. In 1905 Schaudinn discovered the organism; in 1907 the researches of Bordet and Wassermann gave us the complement-fixation test; in 1910 Ehrlich performed his 606th experiment of a series and gave us salvarsan. In the short space of 6 years the new methods for diagnosing and treating syphilis were created.

Surgeon General Parran has pointed out that the first large scale experiment in the use of these weapons was an industrial experiment. It was war time. America's biggest industry—the war industry—was hiring more than five million military employees. An army needs health, and the new instruments against syphilis were used in a demonstration of military medicine that at the close of hostilities became also a popular campaign. That campaign unfortunately was abortive. As Dr. Parran pointedly suggested in his recent address before the American Medical Association, "We apparently thought that the spirochete was demobilized with the army."

In the years since that time the technic of the darkfield has been im-

proved; the complement-fixation has been refined; and the sensitive flocculation tests have added to the accuracy of diagnosis. Within the past half dozen years the Coöperative Clinical Group Studies have given to the treatment of syphilis a precision which it did not have before. During the last 18 months the taboo has been broken. Syphilis is now discussed publicly.

Thus we have medical weapons in a highly perfected state. We have public acceptance and support. The next question is: Is the campaign against syphilis going to be a nine days' wonder, another thing that "something ought to be done about," or will it be translated into definite programs?

Medical historians will judge the fight on syphilis by its results. Those results can be measured only in terms of how many patients come to treatment, how many patients who come to treatment get adequate treatment, and how well also the existing medical facilities contribute to those results.

In this fight public health authorities can expect the coöperation of industrial medical services. Letting syphilis go on is bad economics; industry is alive to economics. Syphilis is a killer, as the Surgeon General has declared. More than 1,000,000 years of life expectancy is lost each year to syphilitic deaths. Syphilis as the cause of aneurysm, paresis, tabes dorsalis, and cardiovascular disease, is a threat to the efficiency and safety which are funda-

* Read at a Joint Session of the National Society for the Prevention of Blindness and the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

mental in the industrial processes. Syphilis, through these diseases, costs America in institutional care between 40 and 50 million dollars every year. Both as a taxpayer and as an employer, industry is interested in all these phases of syphilis. There is no sum which has been suggested for control which approaches the present cost of syphilis to American communities. It has been well said that "the cheapest thing America can do with her million annual cases of syphilis is to cure them."

Some companies, but proportionately not many, have taken steps to meet this problem of syphilis. In the Division of Industrial Hygiene we recently directed letters to more than 200 industrial surgeons. To quote the summary of those studies as presented in the Surgeon General's book, *Shadow on the Land: Syphilis*:

Of 80 companies employing nearly a million persons, only 15 make routine blood tests as part of the preemployment and later periodic examinations. Among a total of 110,675 employees reexamined, 5,313, or 4.8 per cent, were positive. Among a smaller number of applicants (21,239) 2.3 per cent were positive, indicating that those who know they have syphilis seek employment where no tests are made.

The proportion of the amount of testing done among the railroads is somewhat larger. Fifteen railroads, employing 414,684 of America's million railroad workers, reported that they had examined 119,535 of their employees. Some roads reported that virtually all of their employees had been tested. One railroad reported that it had tested 45,000 employees; another reported 20,000 employees tested, another 16,000, and another 8,000. This interest on the part of the railroads goes back for 15 years. More than 10 years ago the railroad surgeons drew up a recommended program for venereal disease control. Their interest stems in large measure from the importance of the safety factor in railroading.

There are two questions involved in the approach of industry to syphilis. The first is the general question of policy. Should blood tests be given? What should industry do to reduce the incidence of syphilis among its workers? What in general should be its attitude toward the employee with a positive Wassermann? The Surgeon General, in his address before the Medical and Surgical Section of the American Railway Association last June, and in an article he published in the September issue of *Factory*, a management magazine, summarized this problem in suggesting:

1. That routine blood tests are desirable for applicants for employment.
2. That routine blood tests are desirable at the time of periodic reexamination of employees.
3. That industry with its compact organization will find the development of a vigorous educational program profitable.
4. That industry might extend that educational campaign into the field of prophylaxis.
5. That there is a responsibility upon the industrial medical officer to see that adequate modern treatment is available to employees at prices ordinary wage earners can afford—that if such is not available in private practice or at public clinics, the industrial medical service should itself undertake such treatment.
6. That syphilis must at all times be handled as merely another communicable disease. The privacy of relations between the worker and the medical service should be conducted in the best professional tradition. In ordinary cases it cannot be regarded as ground for the rejection of applicants or for the dismissal of employees, though treatment may be properly required.

The other principal problem is that of applying this general policy to particular workers and in particular types of jobs. What should industry do about the machinist with syphilis, the crane operator with syphilis, the waitress with syphilis, the plant manager with syphilis, and the chairman of the board of directors with syphilis?

One need not search far to conclude that the policies now applied are often hit or miss. I have in mind the policy

followed until a short time ago by the Civil Service Commission of the United States. It did not ask routine blood tests for syphilis from prospective employees. When, however, the fact was discovered that a prospective employee was infected, he was rejected out-of-hand. Expressions of deep solicitude for the retirement funds were made to explain the policy. A real interest in the retirement funds would have suggested that a policy of routine blood tests, plus the requirement of treatment, but without the policy of discharge, would be far more intelligent.

Or take this case from industry: Some months ago a young man applied for a job in an eastern air craft engine factory. His qualifications as a machinist were found to be high. He was hired. After a week's work he was given a physical examination, which included, as all good physical examinations should, a blood test. His blood test was positive. He was fired.

A few days later he became the patient of a prominent eastern syphilologist. He gave a history of having had a primary chancre some years before. The doctor that he consulted treated it with a "powder," probably calomel. When the secondary rash appeared, he had been advised to take baths in a solution of baking powder. This also had disappeared. Until the time of the blood test he had no knowledge of the true nature of his disease. It may be fairly said that his condition was due to the negligence or ignorance of the "physician" who originally saw his case.

This patient was willing to take treatment, eager to do so. His inability to secure a job, however, jeopardized his ability to pay for such treatment.

The syphilologist protested to the company. He pointed out that in that stage of the disease treatment was a definite bar to central nervous system

complications and a definite protection from infection. The cure was almost certain. He offered to report from time to time on the progress of treatment. At the time the last correspondence relating to the case came to the Public Health Service the syphilologist had not received any reply from the company.

I need hardly say from the point of view of modern medical science that the syphilologist was right; the company was wrong. There was no element of risk involved in this case. By way of contrast it might be worth while to note that in the routine physical examination given to commercial pilots who fly the planes that use the motors that were built in the plant, who have the lives of passengers and the safety of expensive equipment in their hands, the blood test is not included. Yet *only* the blood test can reveal syphilis in the latent stage.

Or take another case from real life: The wife of a member of our staff was riding home in a nearly empty bus one evening when a talkative lady sitting next to her began to discuss the awful case of her maid. The girl, it seems, had been too insistent about her Thursday afternoons off. She had let slip the fact that she was going to her doctor and the scandalized housewife discovered that she had been under treatment for syphilis for nearly a year. The housewife, being highly moral and very timid, fired the maid.

Now obviously, the lady was not one who was systematic enough to ask a routine blood test in advance. Obviously, too, the maid belonged to that small fraction of syphilitics tenacious enough to continue treatment over an extended period. She was non-infectious and of no danger to anyone; in fact she was far safer than many whose blood test showed negative a week or so before.

This, though not a case of industrial

employment, is nevertheless typical of many management decisions with regard to syphilis. It is not dissimilar to the policy of the Civil Service Commission, as cited. Each of you can probably recall a dozen or more similar cases from your own experience.

These cases are worth citing because they emphasize the need for a careful consideration of syphilis and the job. One can lay down broad policies, but he must exercise administrative judgment within the ambit of those policies in terms of two variables: (1) the particular job, its requirements and responsibilities; (2) the particular syphilitic, the stage of the disease and the treatment taken.

When one considers the job there seem to be four principal sorts of human relationships involved. Three of these concern industry—the other, the individual job, is more or less distinguished by the fact that it is not integrated into a larger enterprise, the job of the farmer, the artist, or the prospector, for example.

The most obvious concern when one considers syphilis is the *personal contact job*. This group would include the food handlers, the hotel help, barbers, beauty parlor workers, Pullman porters, matrons, nurses, school teachers, and all whose work brings them into intimate personal relations with other people. It is these that present the greatest possibility of chance infection.

Considered in terms of the various stages of the disease, it is the early stage that is of most importance. The latent syphilitic is not likely to transmit an accidental infection. A paretic cook may spoil one evening's broth, but he is not apt to pass his syphilis on to anyone else. But the primary and secondary stages, when chancres, skin rashes, or mucous patches appear, are important. Anyone who has responsibility for this group of workers must keep high his index of suspicion when-

ever a skin lesion of any kind appears. The darkfield should be freely employed to discover the early cases in that 10 to 20 day period of the first chancre, before the blood turns positive.

The second job group in which syphilis is of importance to industry is the *job of responsibility*. The air pilot or the engineer, responsible for the safety of passengers, the operator of switches or interlocking systems, the train dispatcher, the crane operator, the executive with his financial responsibility for the management and finances of the enterprise, all would fall within a group which presents no extraordinary opportunity for accidental infection, but in which mental or physical failure under stress may have disastrous consequence to the safety of their fellow workers, the public, themselves, the equipment, or even the company.

Among various stages of the disease the first stage has only its public health importance. It is the latent stage and the incipient later stages which concern us. The need of periodic blood tests, of insistence on treatment which will arrest the disease before it enters the central nervous system or threatens an internal organ with aneurysm, is evident. Only the blood test will find syphilis at this stage. You are dealing, moreover, with an extremely valuable group of employees. These complications come in late middle life. The longer their seniority and training the more valuable they are likely to be: the higher they have risen in rank and leadership the sounder is the industrial policy which makes their cure a responsibility of industry.

There is another sort of job group, which I might call, for want of a better term, the *routine job*. Here will fall many of the operators of individual machines, janitors, helpers, and clerks. They present on the one hand no unusual problem of chance infection; on the other hand no physical or men-

tal failure would have large consequences to the work, their fellows, or patrons of the company.

This group of workers presents a problem which is present with the two classes mentioned before. I did not emphasize this because hazards of infection and safety were dominant considerations. If they have syphilis they are sick men. That fact must not be obscured by the fact that they are not bedridden. If they have early syphilis they have an infectious skin lesion which may be passed either venereally or by chance contact to others and will almost certainly be passed to their wives and children. If they have latent syphilis, however complete the apparent peace they have made with the spirochete, there are statements to indicate that they are not the efficient employees they would be without latent syphilis. It is true that there are no accident statistics to cover this point. One can find countless cases to illustrate the slow healing of wounds or bone structure in the case of syphilitics. One can find compensation claims paid for injuries which better medical advice would have set down to syphilitic infection rather than accident. How large this sort of thing bulks in the annual budget of a large industrial organization may be a matter of dispute. It is certain, however, that half a dozen such cases a year would bulk much larger than the cost of a company program for the control of syphilis.

Let us not forget this as we discuss the hazards of syphilis: There is a silver lining to the problem. Treatment is specific, certain in results. It is long, but no other serious disease yields so definitely to the physician. All these hazards are unnecessary if syphilis is found through routine blood tests, if treatment is available and adequate.

Two years ago an advisory committee to the U. S. Public Health

Service was formed to consider the establishment of State and Local Programs for Venereal Disease Control. It included health officials, leading syphilologists. They sifted the experience of Sweden, Denmark, Great Britain, and leading states and cities of this country. They drafted a program which would serve as a blue print for states and municipalities which were setting up public health facilities against syphilis. From Social Security funds, \$8,000,000 had been set aside for public health activities. With new funds available states which had allowed venereal disease control to atrophy were rehabilitating their programs.

That program recommended among other things, free laboratory service available to physicians and private medical services throughout the state. It should be possible, in any state with a well organized program, for companies, such as those many of you represent, to send your blood or dark-field specimens to a central state laboratory for analysis and report.

Such facilities are not yet universal. Where such state laboratories exist they sometimes refuse to perform tests on the large scale required by industrial concerns. There are two answers which may be given: The service is an integral part of the state's program of venereal disease control. It is one which you may properly insist on, using every appropriate resource of pressure to secure it. On the other hand, with the great growth of interest in venereal disease control, many state laboratories cannot expand their facilities rapidly enough to meet these needs. If satisfactory contract arrangements cannot be made with private laboratories, the cheapest way to secure performance of these blood tests would be the hiring of a technician to perform them in your own laboratory. It is work which would not, after the

first few weeks, take the full time of the technician. There are, I believe, few medical staffs that could not make effective use of an additional laboratory person of this type.

This is the solution to the problem applied by Dr. G. H. Gehrmann in Dupont's outstanding program of syphilis control. Tests were done by the company laboratory. Positive results were checked by second specimens and tests. If no definite history of the disease was found, positive tests were double checked by work in independent laboratories.

In Dr. Gehrman's original program the men were then directed to consult their private physicians. The latter were supplied the necessary information with reference to the patient. But Dr. Gehrmann's experience with private treatment of syphilis was not always good. As some clue to what you yourselves may find—perhaps you have already found it—I will quote his own comments on the work. He says:

Each case has been followed persistently by the staff of the medical division to insure continuous treatment, and it is through this follow-up of employees who have been referred to their own physicians for treatment that so much has been learned of the difficulties which make the present plan of handling these cases seem unsatisfactory:

The findings are enumerated:

1. Very few refuse to take their treatment.
2. Most physicians demand prices for treatment that are beyond the means of the individuals and out of reasonable proportion to their incomes. Some physicians maintain these high prices despite the fact that they are receiving arsphenamine, neoarsphenamine, and bismuth free of cost from their state.
3. Many physicians refuse to treat the referred cases, stating that no treatment is indicated, in spite of four plus Kahn and Wassermann reactions although the cases have never received adequate treatment.
4. Numerous physicians refuse to admit that their patients have syphilis (again in the face of four plus Kahn and Wassermann reactions). This group denies the validity of blood tests and states that they have known their patients for years, and further know

that these same patients could not have contracted syphilis without their (the doctors') knowledge.

5. On several occasions the attending physician has sent a blood specimen to a private or state laboratory and the report has come back that the reaction is negative. In every instance the results obtained by the company laboratory have been corroborated by subsequent check, but the attending physician has not always admitted that the patient has syphilis.

6. Many cases are discharged as having had sufficient treatment, after 3 to 10 injections of neoarsphenamine without a heavy metal.

7. Some have been reported as being well after a few mercury inunctions or a few intramuscular injections of water-soluble bismuth.

8. Some are being treated with pills and nothing else.

9. Treatment at the free clinics is very satisfactory but it is not always possible for employees to conform to clinic hours and in some places the clinics refuse to treat any patient who is employed.

The evidence (he refers here to the entire report) presented above indicates that the incidence of syphilis in industry is of sufficient extent to be well worth consideration both from the standpoint of public health and industrial risk. The problem of getting these cases adequately treated is extremely difficult, and the question arises, is it advisable for industry to assume the entire obligation of treating these cases?

There is no question but that this work is well worth while, and there is no question about the adequacy of the treatment which the majority of these infected employees receive. But it does seem advisable for the industry to take over the entire management of these patients and thus insure to them continuous and proper treatment.

At some of the Dupont plants Dr. Gehrmann has since instituted the policy of treating employees suffering from syphilis. His reports would indicate the wisdom of the policy.

I would like to revert in conclusion to what industry may *expect* from state and local public health administrations. I need not discuss the administrative problems of the state and local health officers in detail. The details of these problems are their responsibilities, but there are some phases of syphilis con-

trol which the industrial medical service finds it difficult to handle by itself. Where did the employee with syphilis acquire his syphilis? How shall that source of infection be prevented from infecting others? The responsibility of finding the source of infection and eliminating it before the disease is spread to others is largely a job for the public health authorities, and the industrial medical officer should expect and receive vigorous coöperation in such case finding. Most public health officials will be glad to coöperate in bringing to treatment infected members of the syphilitic's family or those who do not have access to industrial medical care programs.

I need hardly reiterate that the industrial surgeon should expect and receive effective, expert consultation on the problems of control. The industrial medical officer is contributing one of the most effective possible medical units to the public health battalions against

syphilis. He should expect, before long, that adequate facilities be available in every state for his serologic tests. He should receive, along with every other physician, free anti-syphilitic drugs as part of the state program.

Where the industrial medical official does not receive this kind of coöperation, he should state his case clearly to his own management, to his medical organization, and to associations of business men who are coming increasingly to an understanding of this problem. With these as his allies, he should be able to secure action. He will find, in most cases where the health official has not coöperated, that it is a lack of administrative authority under the law or lack of funds that has made it impossible to coöperate effectively. Health officials will, I am sure, welcome such allies in educating legislators and the public to the problems of syphilis control.

Score Cards for Eating Places

SCORE cards for restaurants and other places serving food to the public will be issued by the Washington (D. C.) Department of Health. Establishments will be scored on the basis of rigid inspections of the premises, as well as bacterial determination in utensils, and other checks, one of which is health status of employees. No establishment will be given 100 per cent on the score card without a physician's certificate of health for each

employee. Other checks include: serving of milk in original bottles; posting food signs; obtaining oysters from certified sources; discarding cracked china; and eliminating silver polishes containing cyanide. Records of illnesses among employees must be given to inspectors, including proof that proper medical approval has been given before an employee is allowed to return to work after illness.—*The Health Officer*, U.S.P.H.S., Dec., 1937.

Comparative Methods of Diagnosis of Rabies in Animals*

CHARLES N. LEACH, M.D.

Field Director, Rockefeller Foundation, State Board of Health, Montgomery, Ala.

NEGRI announced his microscopic test for rabies in 1903 which has since been generally followed in routine diagnostic work. A considerable amount of investigation concerning the pathological changes in the central nervous system had already been published. As early as 1892 Babes¹ described his "rabid tubercles." Ganglionic changes occurring in the disease were described by van Gehuchten and Nélis,² and McCarthy and Ravenel.³

Following the announcement of Negri's discovery earlier microscopic methods of diagnosis were gradually succeeded by the Negri body test. It is known that Negri bodies are not always demonstrable in the brains of rabid animals. Joseph Koch⁴ states that 10 to 12 per cent of the brains which are positive on animal inoculation will fail to show Negri bodies when the customary method of examination is employed. This percentage of error, he claims, would be reduced if impressions or smears were taken from ganglion cells and various parts of the brain instead of from the Ammon's

horn alone. The percentage of error will probably vary also with the prevalence of the disease in the geographical areas from which the material for diagnosis is obtained. In regions of high endemicity one might expect a high percentage of Negri negative specimens proving positive on animal inoculation.

Negri found peculiar intracellular bodies occurring with a high degree of constancy in different parts of the central nervous system, especially in the Ammon's horn of the hippocampus major or in the Purkinje cells of the cerebellum. These bodies exhibit marked variations in size; the diameter varying from 1 μ to 27 μ . In form they may be round, oval, or, in the larger bodies, pear shaped. The internal structure is reticulate and usually contains one or more vacuoles. The bodies are surrounded by a clearly defined membrane.

The injection of brain emulsion from rabid animals into rabbits and guinea pigs is uncertain in its results after incubation periods of 2 to 8 weeks. In consequence of the long incubation period and uncertainty of infectivity in these animals, their use has been very limited in recent years.

Mice have been tried as test animals by European workers, but have not proved satisfactory. Babes⁵ in 1887

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

The studies and observations herein reported were conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation and the Alabama State Board of Health.

reported that they were susceptible to rabies. He stated that they develop the furious type of the disease and that great care should be exercised in handling the animals during the late stages of the disease because of the danger of being bitten. Gerlach⁶ reports a series of 26 white mice injected with street virus from Negri positive brains, only 17 of which died of rabies. He does not state how the injections were administered and does not recommend the white mouse as a test animal.

A questionnaire was sent to all state laboratories in the United States asking if confirmatory animal inoculations were employed with Negri negative material. Replies were received from 39 states, and 5 reported that all Negri negative material was being injected into rabbits or guinea pigs. Five laboratories stated that they occasionally checked their Negri negative material by animal inoculation. Among the above 10 states employing animal inoculation for the diagnosis of rabies, 5 listed the guinea pig as the animal of choice and 4 the rabbit, while one laboratory uses the guinea pig and rabbit on each specimen examined. The reasons given for not employing the confirmatory animal test included the following: (1) delay in obtaining a result, (2) inadequate facilities for housing animals, (3) cost of laboratory animals.

Webster and Dawson⁷ have described an improved method of diagnosis by mouse inoculation. They make use of a special strain of white mice supposedly bred for special susceptibility to neurotropic viruses. Four to 6 weeks old white mice are highly susceptible to the rabies virus when inoculated intracerebrally with brain emulsion from a rabid animal. The mouse technic as practised in this laboratory is as follows:

Material, when not examined fresh, is preserved in full strength glycerin. A

small portion of the Ammon's horn is ground up in a sterile mortar and 9 parts of hormone broth added to 1 part of ground brain material. This is thoroughly emulsified and then centrifuged at 2,000 to 2,500 revolutions per minute for about 5 minutes. With a 0.25 c.c. tuberculin syringe, 0.03 c.c. of the supernatant fluid is injected into the brain through the skull of a 4 to 6 weeks old mouse. A 27 gauge needle, $\frac{1}{4}$ " long is employed, and the injection made slightly to one side of the mid line of the skull and half way between the eye and ear. The site of inoculation is moistened with alcohol before injecting. The mice are lightly etherized before the operation. It has been our practice to inoculate 4 mice with each brain specimen. When the injections are performed by experienced technicians, one can expect a mortality of 0.5 to 1.0 per cent due to mechanical injury. In our series of 1,032 brain specimens we have employed 5,339 mice with a mortality of 1.7 per cent due to mechanical injury. This is higher than usual and may be explained by the fact that many of the injections were performed by persons learning the technic.

Table I gives an analysis of the findings on 1,032 specimens from various animal brains received from Alabama, Georgia, West Virginia, Connecticut, and Havana, Cuba. Of the total received, 338 specimens were reported positive by the diagnostic laboratories, 690 negative, and 4 questionable. Among the 338 specimens reported positive for Negri bodies, 3 proved negative on mouse inoculation; 83 of the 690 reported negative (12.0 per cent) produced typical symptoms of paralytic rabies in the mouse, and Negri bodies were demonstrated in the mouse brain. Three of the 4 specimens reported as questionable by the diagnostic laboratories proved positive on intracerebral mouse inoculation.

TABLE I

Comparative Diagnostic Results by the Usual Laboratory Methods and the Mouse Inoculation Technic

In an effort to determine the relative susceptibility of the true field mouse (*Peromyscus polionotus polionotus*—Wagner) and the Webster-Dawson strain of white mouse, a group of white mice and field mice were injected with brain emulsion from 11 different animals. The same supernatant fluid from each specimen was injected at the same time into mice of the two groups.

Table II shows a slightly greater resistance to the rabies virus on the part of the field mice. This may be due in part to the fact that some of the field mice were well over 6 weeks of age, as could be determined by the ossification of the skull. The needle was forced through some of the skulls of field mice with greater difficulty than was the case with the younger white mice of known age. The field mice were much more excitable and difficult to handle, and in some cases the furious type of rabies was produced, whereas among the 5,339 white mice inoculated, none has shown the furious type.

When the disease appears among a group of inoculated mice, in the great

majority of instances all mice in the group succumb. One survivor has been observed from each of 4 groups, and in 3 groups there were 2 survivors in each of 4 inoculated. The survivors may show early symptoms and later recover, but no recoveries are recorded after the disease reaches the paralytic stage.

After the development of paralysis, death follows on an average of approximately 48 hours. Sluggishness, roughening of the fur and loss of hair luster appear as the earliest symptoms, followed by photophobia in many cases and a conjunctivitis with sero-purulent discharge. Paralysis, most frequently of the hind legs, appears and the legs are extended either to the sides or straight back. At this stage convulsions are frequently seen, especially when the animal is disturbed by jarring or noise. Death is preceded by complete prostration and labored and irregular respiration. Of the 2,095 mice injected with rabies positive brain material, the majority died in from 10 to 12 days.

An occasional mouse inoculated intracerebrally with brain emulsion from a

positive case showed Negri bodies as early as the 5th day after injection. On the 6th day following intracerebral inoculation with Negri positive brain, 226 of 289 (78.2 per cent) mice examined were Negri positive and 3 doubtful✓

It has been the experience of this laboratory that in brain material from animals vaccinated against or treated for rabies, Negri bodies are more difficult to demonstrate in the original material. The disease, however, can be produced in mice, with the production of Negri bodies, by inoculating with material from the brain✓

A human brain from an adult dying of rabies following a face bite inflicted by a proven rabid dog was submitted for examination. This patient started treatment the day following the bite and received 3 injections a day for 15 days. The patient developed rabies 21 days after exposure, and the brain was found negative for Negri bodies on repeated examinations. Mouse inoculation with this material proved positive, and Negri bodies were present in the mouse brain on the tenth day after intracerebral injection. When a vaccinated dog develops the disease, it is usually of the paralytic or "dumb"

type, and the experienced veterinarian's diagnosis is of the utmost importance, as the Negri diagnosis is unreliable. In these cases the intracerebral injection is of particular value.

The mouse test offers a cheaper and more rapid method of diagnosis than is the case with the guinea pig or rabbit. Mice purchased from dealers cost 15 cents each but can be bred with little difficulty, thus reducing the cost. Reactions to rabies virus when injected intracerebrally into the mouse are very consistent and offer a reliable means of verifying the routine microscopic Negri technic.

SUMMARY

A technic for the earlier diagnosis of rabies by mouse inoculation is described. In addition to shortening the period required for animal diagnosis the method has the advantage of consider-

ably reducing the cost. Comparative results from brain material of 1,032 animals diagnosed by the usual methods in several laboratories and then injected into mice confirmed the positive results obtained by the usual methods, but disclosed an error of 12.0 per cent for the brains reported negative for Negri bodies.

The vaccination or treatment of animals with rabies vaccine apparently increases the difficulty of diagnosis by the discovery of Negri bodies.

Animal and Human Diseases

. . . Animal disease has a close connection with human disease, and students of public health will find much to think over in the Ministry of Agriculture's *Report of Proceedings under the Diseases of Animals Acts for the Year 1936*. Bovine tuberculosis is but one of the many subjects dealt with. It was reported to exist on 26,744 premises, and after examination by veterinary inspectors, 23,802 animals were

ordered to be slaughtered, an increase of nearly 1,500 on 1935. The number of Attested Herds was 55 at the beginning of the year, and rose to 140 on 31st October, after which a rapid increase brought the total to 192 at the end of the year. (During the first quarter of the present year 58 further herds were added to the register.)—*J. Roy. Inst. Pub. Health & Hyg.*, 1, 2 (Nov.), 1937.

Tuberculosis Among Children and Young People in Cattaraugus County, N. Y.*

JOHN H. KORNS, M.D.

Director, Bureau of Tuberculosis, Cattaraugus County Department of Health, Olean, N. Y.

IN discussing the problem of tuberculosis among children and young people in Cattaraugus County, one may well take into consideration various factors such as the population density and its composition, the prevalent occupations, the economic level, past and present tuberculosis mortality rates for all ages, and the antituberculosis agencies or facilities available. Tuberculosis among children is and in recent years has been only a minor health problem in this county. For this reason, and because of the importance of coördinating if possible the administrative control of tuberculosis in children with that in adolescence and early adult life, the writer has taken the liberty of extending in this presentation the age period up to 25 years.

The county lies among the foothills of the Allegheny mountains in southwestern New York. Its area is 1,343 square miles. Its population of 72,000 which has been almost stationary since 1920, is rural and semi-rural except for 31,000 persons residing in two small cities. The county is remote enough from large cities not to be suburban. Ninety per cent of the population are native born whites. There are about

1,000 Indians in two reservations and about 450 Negroes who live mostly in Olean, a city of 22,000. Agriculture, particularly dairying, is the main occupation, although about one-third of the inhabitants are in some form of industry. Only a few of these industries, however, appear to carry a tuberculosis hazard. Economically the county ranks in the upper third of the rural counties of New York State.

The crude mortality rate from tuberculosis was low for the county compared with that for New York State, when the County Health Department was organized in 1923, being for that year 72.6 per 100,000 for the county and 97.9 for the state. During the 5 years prior to 1923, the rate in the county was stationary, while since that time there has been a progressive decrease. Divided roughly into 5 year periods, the annual mortality rate for all forms of tuberculosis was:

	<i>Per 100,000</i>
1918 to 1922 inclusive	69.6
1923 to 1927 inclusive	55.7
1928 to 1932 inclusive	42.5
1933 through June 1937	28.9

Beginning with 1916, a County Tuberculosis Sanatorium has been available for the free care of resident tuberculous patients. Up to 1923 the institution had only one public health nurse

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

for field work. Since 1923 there has been a comprehensive, full-time County Health Department, with an adequate number of public health nurses for field supervision and a Director of the Bureau of Tuberculosis. For the greater part of this time the Director has been, concurrently, the Superintendent of the Sanatorium. He has conducted diagnostic clinics throughout the county, to which physicians have referred patients and to which nurses, with the physicians' consent, have invited contacts of tuberculosis patients. A consultation service in patients' homes has been furnished the physicians throughout the county. Both in clinics and consultations a portable X-ray equipment has been used. In addition, a tuberculin and X-ray survey was made among Reservation Indians because of their high tuberculosis death rate. X-ray surveys of juniors and seniors in high schools and of school teachers have been made as educational and case finding measures. Tuberculosis eradication among cattle has been a recent development, begun in 1923 when 58,928 head were tested with 7.1 per cent reactors. Elimination of reactors proceeded so rapidly and supervision of cattle has been so thorough that for the last 5 years less than 0.5 per cent have reacted.

TUBERCULOSIS AMONG CHILDREN

Under the conditions outlined, particularly with a low and steadily declining total tuberculosis death rate, one would expect very few to die from tuberculosis in infancy and childhood. Such is the case. During the past 15 years there were 17 tuberculosis deaths under 15 years of age, and none has occurred among county residents in this age group since 1932. On analysis this shows the annual tuberculosis specific death rate to have been, approximately, for whites under 15, 4 per 100,000 and for Indians, 137.

Data on tuberculin tests and diagnoses cover only the period since the beginning of 1928, and less accurately for Indians than for whites. In the past 9½ years only 9 whites and 5 Indians under 15 have been found to have reinfection tuberculosis. In addition some were seen with cervical lymph node lesions but these were considered primary. Tuberculin testing has been a routine procedure for all clinic children under 16. Those children who were not known to have been exposed to a positive sputum were observed to respond quite infrequently to 0.1 mg. of Old Tuberculin intradermally. This entire group of 2,621 clinic children tested during the 9 years prior to 1937 showed an incidence of 9.2 per cent positive reactions. Further sub-divided, during the first 3 years of this time the percentage of reactors was 15.6, while during the last 6 years it was only 4.8. About half were in the 10-15 year age group, and inasmuch as the composition of the clinic and the distribution by age were similar during the whole period, the figures suggest strongly that the so-called non-contact child is being infected less frequently than a few years ago. The clinic children under 16 tested during 1936, numbering 226, heavily loaded by 28 per cent of intimate tuberculosis contacts, showed only 11 per cent positive. A tuberculin survey of children in 85 rural and village schools showed 8.2 per cent positive among 1,183 tested under age 16, the majority being 10 years of age or older. A similar survey of 226 Indian children under 15 revealed 23 per cent positive reactors. This higher incidence of infection among Indian children is not surprising in view of the fact that the total Indian tuberculosis death rate has been in recent years 6 times that among whites. On the basis of the rarity of tuberculosis deaths among children, the infrequency of reinfection tuberculosis

before age 15, the apparent mildness of primary tuberculosis, and the decreasing incidence of tuberculous infection in the same age period, the administrative measures which have been adopted and which are at present operative aim at less medical observation and care of infected children than formerly. Primary tuberculosis is not institutionalized but is kept in the home, while the open case, if found, is removed and treated. Re-X-raying of positive reactors with or without demonstrable primary lesions is not done until 14, from which age annual X-ray examinations are done until 25. Exceptions are made of course where exposure continues or symptoms develop. Adequate home observation by nurses is available and private physicians are coöperative. These conditions are important prerequisites to this plan. This shifting of emphasis from tuberculosis during childhood came about not only because of the relative unimportance of the problem but because of the questionable value of the former plan of placing children with primary tuberculosis in an institution. In our experience, some of these children with primary lesions, in spite of prolonged institutional care in childhood, proceed to develop in adolescence reinfection tuberculosis even though no known exogenous reinfection occurs. The two instances of this kind recorded in the past 10 years were in girls who had had prolonged exposure within the home as little children prior to the breaking of the contact and who had shown X-ray evidence of primary lesions in the chest.

TUBERCULOSIS IN ADOLESCENTS AND YOUNG ADULTS

What concerns the tuberculosis workers in Cattaugus County more than the tuberculosis problem in children is the problem in adolescence and early adult life. It is believed that while many of those developing rein-

fection tuberculosis between ages 15 and 24 have been infected as infants or small children within the home, a still larger number probably have their first infection during or after the high school age and from sources outside the home. This belief is based partly on the low incidence of positive tuberculin reactions under 16 and partly on the failure to trace the source of the infection to the home in the majority of the adolescent and early adult cases. Routine examination of household contacts for several years enables one to speak with some assurance on this point.

Since the beginning of 1928, 106 persons between ages 15 and 24 have been found to have reinfection tuberculosis. In only 31 instances was it at all definitely established that the primary infection had occurred within the home. In a few it was strongly suspected to be among schoolmates or other associates outside the home. Theoretically, then, were all the tuberculosis families in a community known to the health department and, over a period of years, their contacts were properly examined, less than a third of the secondary reinfection cases in the above age group might be discovered, unless additional case finding methods were used.

In view of facts like these, the question arises as to how one can coördinate a tuberculosis program for young people with that for children. Methods followed and results obtained in Cattaugus County may be noted to see whether any light is thrown on the problem. Tuberculosis deaths under age 25 during the past 15 years numbered 105, an average of 7 per year. Subdivided roughly into three 5 year periods, the annual deaths averaged for the successive periods approximately 11, 7, and 3, so that there has been, in this age period, an encouraging decline in deaths. Analyzed for whites and Indians (there being no bona fide

TABLE I

Tuberculin Reactors Observed Roentgenographically for Periods Varying from 3 to 12 Years

Age, in Years at End of Observation Period

tuberculosis deaths among Negroes) these figures show an annual tuberculosis specific death rate per 100,000, under 25, for the three periods to be approximately as follows:

	Whites	Indians
1923 to 1927 inclusive	28	475
1928 to 1932 inclusive	17	295
1933 through June 1937	9	93

Forty-nine of the above 105 deaths occurred since the beginning of 1928, and 42 of these were in the 15-24 year age period, 55 per cent being females. The 106 cases of reinfection tuberculosis in the 15-24 year age period which have been recorded since 1928 have come to light through three sources (1) clinic patients referred by physicians; (2) cases reported by institutions outside the county; (3) cases discovered through the routine follow-up of juvenile tuberculin reactors, or through group X-ray surveys by the County Health Department. Ninety-one of the cases were referred by physicians for diagnosis, or confirmation of diagnosis, or were referred by institutions, while 15 came as a result of the department's observation which often had begun

many years earlier. Those in the larger group nearly all had had symptoms at the time of diagnosis while those in the smaller group did not. This is reflected in the classification of cases of pulmonary tuberculosis at the time of diagnosis which showed in the larger group 26 per cent in the minimal stage and in the smaller group 67 per cent. Since January, 1936, 47 per cent of all new reinfection cases under age 25 were found as a result of routine follow-up of reactors or the X-raying of groups and of these 86 per cent of the pulmonary cases were in the minimal stage.

COORDINATION OF ADMINISTRATIVE METHODS FOR CHILDREN AND FOR YOUNG PEOPLE

To illustrate the type of medical supervision of juvenile reactors practised by the County Department of Health, two tabulations have been made. Table I shows for 377 reactors the age at the beginning of observation and for all but 90 of them the age to which observation has been extended up to August 1, 1937. (For the sake of brevity the 90 reactors whose ob-

servation has not yet continued to age 15 are totalled in one column.) These observations cover 2,382 person-years and include 1,966 X-ray examinations of the chest. Table II shows the tuberculosis findings resulting from the above observations. In Table II one is struck with the large number who have developed reinfection tuberculosis among those reactors previously exposed to open cases, and the relatively small number among those reactors not known to have been so exposed. Fourteen among 119, *i.e.* 11.7 per cent, of those reactors known to have had household exposure to a positive sputum have up to the present developed reinfection tuberculosis, while only 3 among 198, or 1.5 per cent, of those reactors not known to have had such exposure have done so. It will be noted also that those reactors showing X-ray evidence of primary lesions appear to develop reinfection tuberculosis in a much higher percentage than do those without such demonstrable lesions.

This appears to give a definite clue as to where much of the reinfection tuberculosis will be found in young people. It will be among those who

have had intimate exposure to open tuberculosis. Naturally among children this is, commonly, within the home. It is self-evident then that this phase of preventive work—for early diagnosis is preventive work—among adolescents and young adults may be closely linked with that among children.

One is much less certain how to secure early diagnosis among the larger group of young people who give no history of intimate contact. There is, perhaps no compelling reason why the private physician should not enter as a leader the field of preventive medicine and tuberculin test children and young people repeatedly on a wide scale, then have the reactors X-rayed. Ordinarily, however, he does not do this, but waits until the patients seek him. They seek him because of symptoms, and by the time symptoms have developed most of these young people showing tuberculosis have moderately advanced or advanced lesions.

ADDITIONAL ADMINISTRATIVE METHODS AMONG YOUNG PEOPLE

The tuberculosis problem among young people is causing concern in many areas both in this country and

TABLE II
History of Exposure and X-ray Findings Among Tuberculin Reactors

Number of Reactors	<i>In Known Contact</i>		<i>In Probable Contact</i>	<i>Having No Known Contact</i>	Total	<i>Reactors Developing Reinfection Tuberculosis</i>
	<i>In Known Contact With Open Tuberculosis</i>	<i>With Tuberculosis Not Shown To Be Open</i>

Showing no X-ray evidence of primary tuberculosis	63	34	12	165	274	6 2.1%
Total	119	46	14	198	377	
Reactors developing reinfection tuberculosis	14 11.7%	0	1 7.1%	3 1.5%		18* 4.7%

* Among these reinfection cases are included three under 15 years of age. Of these, 2 were pulmonary and 1 osseous.

abroad. It is easy to say that the X-ray examination is the method which must be generally adopted, and it is true. It is certain that if physicians and young people became tuberculosis conscious and demanded a far wider use of X-rays, the proportion of cases diagnosed in the minimal stage would be greatly increased. Here one enters the fields of health education and economics, both of which are fundamental in dealing with tuberculosis.

In Cattaraugus County the matter of early diagnosis in young people is receiving consideration. Some progress can be recorded. If the last decade be divided into two 5 year periods, in the first of these only 20 per cent of those between 15 and 24 years of age showing pulmonary tuberculosis were diagnosed in the minimal stage, while in the second 5 year period 55 per cent were so diagnosed. Besides the X-ray follow-up of clinic reactors, numerous X-ray surveys of juniors and seniors in high school have been made. Among 2,400 students X-rayed in this way only 3 reinfection cases were discovered. A tuberculin and X-ray survey of 650 Indians did not reveal new active tuberculosis at the time but resulted in adding to the roster many tuberculin reactors in the 15-24 year age group. Subsequent reexamination of these has revealed 2 cases of pulmonary tuberculosis. The County Health Department offers at film cost X-ray services to all juniors and seniors in high school annually, to freshmen in the one college within the county, to nurses in hospitals, to young pregnant women, and to young workers in industry. The physicians are encouraged to use widely the free clinic and consultation X-ray service offered by the department and the free service for examining sputum offered by the County Laboratory. The coöperation of physicians is eagerly solicited to the end that prolonged isolation of open cases may be enforced.

Even compulsory institutional care through court order has been resorted to. As for direct educational efforts, these include conferences with patients, family members, and physicians, talks to high school students and teachers and to Parent Teachers' Associations, distribution of literature especially in high school, and the use of the press and the radio. While these methods may all be helpful, it is felt that the X-ray examination of a young person's chest, with a word of explanation added, serves as useful an educational purpose as any.

While high school students are more accessible for examination than others of this age, a large proportion, though fewer than formerly, leave school at the 8th grade. Those going early into industry are now being X-rayed in many instances as a result of more stringent requirements of insurance companies which provide compensation.

There would seem to be justification for repeated X-ray surveys of apparently healthy young people for the reason, already stated, that more than two-thirds of the reinfection cases in this age period could not trace their source of infection, and for the additional reason that occasionally through such surveys young persons may be diagnosed who are still being exposed to mild, unreported but open cases of pulmonary tuberculosis in the home or elsewhere.

The data assembled in this paper show a definite concentration of new cases among the contacts. It must be remembered that these data represent concentrated effort in this group as well. If the entire youth of the county were X-rayed as intensively and persistently as this group has been, the yield of reinfection cases in the larger group undoubtedly would be higher.

The above methods are mentioned not because they are unique or because they have been particularly successful.

Until something better is found, however, it seems worth while to follow them. Reviewing the work of the past decade, it would seem that the most important single factor in helping reduce the tuberculosis deaths among children and young people has been the consistent effort to place positive sputum patients in a sanatorium or otherwise isolate them, and to keep them under such isolation until sputum is negative. The open case is being admitted to a sanatorium with more promptness following diagnosis than was the case a few years ago. There is no waiting list for admission to the sanatorium. At present there are only 3 positive sputum patients known in the county who are not in sanatoria or who have not had sanatorium training and care.

One method of attacking the problem that has not been used is attempted artificial immunization. The department still operates on the theory that it is better for the child to grow up without infection with tubercle bacilli. Possibly sometime this view will be discarded. In any case, there is no doubt general agreement that heavy exposure to virulent tubercle bacilli in childhood constitutes a health liability likely to handicap the child's future, and that this should be prevented by public health organizations, in coöperation where possible with physicians, voluntary health organizations, and hospitals.

No doubt the most economical method of securing early diagnosis in young people in Cattaraugus County theoretically would be to perform periodic tuberculin tests on a large scale, particularly among adolescents, fluoroscoping the reactors. There are in this county, however, practical difficulties in this plan: (1) In a large proportion of instances consent cannot be obtained for routine repeated tuberculin tests, except in established clinics where the young person usually is ex-

amined because of known exposure or because of a physician's request. (2) Fluoroscopy is relatively less valuable than the X-ray film and entails a great deal of time and labor on the part of the physician, since it cannot be delegated to a technician.

CONCLUSIONS

1. Tuberculosis among children in Cattaraugus County is a minor health problem. This is natural as there is a low, progressively decreasing total tuberculosis death rate; the tuberculosis infection incidence among children also is low and appears to be decreasing.

2. Children with primary tuberculosis are not placed in institutions, but persons with open reinfection tuberculosis are isolated promptly, usually in sanatoria. This probably has been the most effective measure in keeping tuberculosis among children at a low level and in reducing the incidence of infection.

3. Tuberculosis in adolescents and young adults is a more serious problem in Cattaraugus County though it appears to be less disturbing than it was a decade ago.

4. Besides the importance of close X-ray observation through adolescence into early adult life of those who have had childhood exposure to tuberculosis—a procedure which will disclose the highest percentage of reinfection cases—a wide use of the X-ray, with or without preliminary tuberculin testing, among young people in high school and in industry, is useful in increasing the proportion of minimal cases of pulmonary tuberculosis discovered. These measures have educational as well as diagnostic value. Practically, when funds are limited, intimate contacts of open cases should be repeatedly examined by X-ray. This should be done thoroughly first. Then, if there are additional funds and facilities, other groups of young people may be similarly examined.

Use of Dishwashing Machines: Pasteurization of Eating Utensils*

WESLEY C. COX, M.D.

Lieut. Colonel, Medical Corps, U. S. A.

Laboratory Service, Walter Reed General Hospital, Army Medical Center, Washington, D. C.

AN investigation of machine dishwashing conducted at the Army Medical Center, Washington, D. C., during August, 1935, showed that the machines were improperly operated and in many instances the processed utensils had organisms of the respiratory and intestinal groups on their surfaces. A study of the fundamental principles of mechanics, thermodynamics, chemistry, and bacteriology involved in machine dishwashing was undertaken in order to determine the optimum operating temperatures and time periods for the wash and rinse processes. The 21 machines in daily use in the wards, messes, and restaurants of the Post, consisting of 19 intermittent type, single tank machines, a single tank conveyor machine, and a multiple tank conveyor machine, furnished adequate material. An automatically controlled intermittent type single tank machine¹ developed as a result of this investigation, was installed during these studies.

Speed is an essential requirement in machine dishwashing, especially during periods of peak load. The utensils must be freed of soil and bacteria and

rendered physically and bacteriologically clean in a minimum time. This is accomplished by the action of the wash and rinse processes, which differ in operation in the single and multiple tank machines. In the single tank machine the wash water is pumped from the wash tank and sprayed over the surfaces of the utensils; the water then passes through the wash tank strainers or screens which retain the major portion of the soil removed from the utensils; reenters the wash tank; and is recirculated. Small particles of soil and bacteria pass through the strainers and are deposited upon the surfaces of the utensils. At the termination of the wash process, although all visible soil may have been removed from the surfaces of the utensils, they are still contaminated in direct proportion to the bacterial content of the wash water. The final cleansing of the utensils is accomplished by the action of the rinse water which is supplied to the machines from the hot water line. The rinse water is sprayed over the utensils, enters the wash tank diluting the detergent solution, overflows into the trap flushing away particles of soil and unsaponified grease. Reduction of the number of organisms in the wash water is effected during each rinse process.

*Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

Multiple tank machines are equipped with separate tanks from which the wash and rinse waters are continuously circulated over the surfaces of the utensils. The action of the wash process is identical with that of single tank machines. The utensils reach the rinse process contaminated with minute particles of soil and bacteria which together with soil and bacteria on the conveyor belt are flushed into the rinse tank by the action of the rinse sprays and recirculated. Unless there be a final rinse with clear water, supplied directly from the hot water line, the utensil surfaces will remain contaminated with soil and bacteria.

The deposit of bacteria on the surfaces of utensils during the wash and rinse processes was demonstrated by processing sterile Petri dish bottoms (150 x 15 mm.) at 100° F. in tap water seeded with broth cultures of test organisms. Agar pour plates were made following processing in this manner, and read after 48 hours' incubation at 98° F. Table I shows the results obtained in single tank machines seeded with a mixture of broth cultures of *B. coli* and *Staphylococcus aureus*.

Any factor which favors the deposit of bacteria on the surfaces of utensils during processing, or protects organisms so deposited from free detergent and thermal action, lowers the efficiency of the wash and rinse operations.

The detergent and thermal actions of the wash processes are important. An effective detergent aids in the rapid removal of soil from utensil surfaces without causing precipitation of insoluble alkaline salts and gummy alkaline soaps, which, when present, are deposited as a sticky film upon the utensil surfaces by the mechanical action of the wash process. Three detergents were tested: (a) trisodium phosphate technical; (b) issue washing

TABLE II

Comparison of Bacteria Counts of Utensils Processed with Trisodium Phosphate, Issue Washing Soda and the Schwartz and Gilmore Detergent

<i>Detergent</i>	<i>Number of Utensils Tested</i>	<i>Average Number of Organisms per Utensil</i>
Trisodium Phosphate	288	41
Issue Washing Soda	288	32
Schwartz and Gilmore Detergent	288	17

soda containing 25 per cent sodium bicarbonate and 60 per cent sodium carbonate; (c) a compound developed by Schwartz and Gilmore² containing sodium hexametaphosphate. The comparative amounts of precipitate formed by these detergents upon addition to hard water was demonstrated in the following manner: A 0.25 per cent solution of each detergent was prepared in tap water of 5 grain hardness and compared in the photometer with a distilled water standard and 0.25 per cent solutions of the detergents in distilled water. The standard and the solutions of the detergents in distilled water gave readings of 100. The readings of the tap water solutions were as follows: Schwartz and Gilmore detergent, 99.7; trisodium phosphate 93.0; issue washing soda 78.0.

These detergents were used over a period of 60 days in dishwashing machines of similar type in 3 different

ward diet kitchens. At the end of the test period the utensils and the interior of the machine using the Schwartz and Gilmore detergent were free of film. The machines in which trisodium phosphate and issue washing soda were used were heavily encrusted with film and it was necessary to hand scour the dishes, glasses and silverware processed, at weekly intervals, in order to remove the film. Film is not only unsightly but forms a protective coating for bacteria which are caught on the gummy surface, reducing rinse efficiency. The insoluble salts and soaps when present are carried over into the rinse tank in multiple tank machines and cause film deposit during the rinse process. Sodium hexametaphosphate prevents the precipitation of insoluble alkaline salts and soaps responsible for film formation by forming soluble complexes with the calcium and magnesium ions present in the wash water, and permits free mechanical, detergent, and thermal action throughout the wash and rinse operations.

Hall³ and Hall and Schwartz⁴ have shown that under similar conditions, utensils processed with the Schwartz and Gilmore detergent were bacteriologically cleaner than those processed with trisodium phosphate. Bacteria counts were made daily, using the swab method, during the period the 3 detergents were under test. The utensils processed with the Schwartz and Gilmore detergent had fewer organisms on their surfaces than those processed with trisodium phosphate or issue washing soda. The results of these tests are shown in Table II.

Hall and Schwartz⁴ and Mallmann⁵ have reported germicidal activity for various detergents when tested under laboratory conditions. In actual dishwashing practice it is impossible to evaluate the bactericidal activity *per se* of a detergent because of the constant

changes in concentration, chemical composition, and pH which take place during the wash and rinse operations.

Heat is the only active bactericidal agent of the wash and rinse processes unless there be an active germicide, such as chlorine, present in the solutions. The number of non-spore-bearing organisms in the wash water of single tank machines and in the wash and rinse waters of multiple tank machines is in inverse ratio to the temperature used. Each succeeding load of utensils should be processed in water containing a minimum of organisms: This is accomplished when thermal death of non-spore-bearing organisms entering the wash and rinse tank waters is effected prior to the processing of the next load of utensils. The survival of bacteria from run to run results in heavy bacterial contamination of the wash and rinse waters. Cumming and Yongue⁶ reported an increase in the number of organisms per c.c. of wash tank water from 12,000 to 250,000 in a 5 hour period. Krog and Dougherty⁷ reported over 900,000 organisms per c.c. in a sample of wash water from a public diner. The bacteria count of the wash tank water of a multiple tank machine operated at 120° F. for 90 minutes increased from 317 per c.c. to 24,600 per c.c. The count of the rinse tank water, operated at 140° F. increased from 7 per c.c. to 2,800 per c.c. during the same period. Under identical conditions using a 165° F. wash and a 180° F. rinse, the wash water count increased from 27 per c.c. to 184 per c.c. and the rinse water count from 1 per c.c. to 18 per c.c. The bacteria count of the wash water of an intermittent single tank machine operated for 90 minutes using a 120° F. wash and a 140° F. rinse, increased from 326 per c.c. to 22,800 per c.c. Using a 160° F. wash and a 180° F. rinse, the bacteria count per c.c. of the

wash water increased from 5 per c.c. to 41 per c.c. Table III shows the results of the operation of single and multiple tank machines for a standard time period at varying wash and rinse temperatures.

The wash tank water of intermittent single tank machines is subject to changes in temperature during operation. Air at room temperature enters the wash chamber during the loading and unloading, cooling the walls of the machine and the residual water in the exposed wash lines. The utensils and rack enter the chamber at room temperature. An average period of 10 seconds is required to bring the utensils and chamber walls to the temperature of the wash tank water. During this period the cooler water returning to the wash tank lowers the temperature of the wash tank water. The average reduction when the wash process is

operated between 140 and 160° F. is 3°. The sources of heat used in mechanical dishwashing are not flexible enough to overcome this drop immediately, and from 10 to 15 seconds are required to return the wash water to the original temperature. The wash water of multiple tank machines is not subject to these variations. Rinse water delivered to the machine by exposed hot water lines is subject to cooling between runs. The reduction in wash water temperature may be overcome by processing at a temperature 3° F. higher; that of the rinse water by proper installation of the hot water lines.

The efficiency of the wash process of all types of machines is affected by: (a) the thoroughness of the scraping of the utensils. (b) the position of the utensils in the wash chamber. and (c) the mechanical action and pattern of

the wash sprays. The removal of all possible soil by efficient scraping reduces the soil load and conserves detergent powder. Proper position of the utensils is necessary; if crowded together full detergent action of the wash water is not obtained. Glasses, bowls, and deep lipped utensils must be placed on edge in order to avoid accumulation of wash water thus preventing detergent action. Spray nozzles and rinse lines may become clogged with particles of soil, causing dead areas which escape effective processing. The manufacturer's setting of the wash and rinse sprays must be preserved, for if the streams of water strike each other the detergent force is reduced to zero.

Utensils soiled with moist proteins (egg albumin and egg yolk), and protein and starch mixtures (mashed potatoes) are readily processed at wash water temperatures from 140 to 190° F. without "cooking" action. Dried protein and protein and starch mixtures are difficult to remove at any wash water temperature. Utensils so soiled should be soaked in water prior to processing. All visible traces of moist "soft boiled" egg yolk and mashed potatoes were removed from utensils during a 30 second wash process, while it required a minimum wash process of 120 seconds to remove similar amounts of dried egg yolk and mashed potatoes.

The rinse process of single tank machines should be operated only for suf-

ficient time to flush the utensil surfaces thoroughly. Excessive rinsing causes dilution and waste of the detergent used. Rinse efficiency is in direct proportion to the force and temperature of the water. Effective rinsing is obtained in 10 seconds in single tank machines at 180° F. and 30 to 50 lb. pressure. A 20 second rinse at 180° F. should be used in multiple tank machines equipped with rinse tank only, in order to effect thermal death of non-spore-bearing organisms carried over from the wash process.

Cleanliness of the working parts of machines is essential. Spray nozzles should be detached and cleaned daily. The interior of the chamber, the strainers, tanks, the door grooves and overlaps should be cleaned after each period of use. Massive contamination of the wash and rinse waters results unless the machines are kept clean. Bacteria counts as high as 50,000 per c.c. were obtained from samples of wash water from dirty single tank machines. These machines were operated as usual but purposely permitted to go without cleaning. The wash tank strainers were emptied but not cleaned and the wash tanks were not flushed after emptying. After standing for 14 hours at temperatures from 78 to 90° F. the wash tanks were filled with clear tap water and the machines operated for a period of 2 minutes. Following this, samples of the wash waters were obtained for bacterial count. Table IV gives the results of the wash water counts.

Cumming and Lynch⁶ and Cumming, Spruit and Reuter⁹ showed that used eating utensils were contaminated with organisms of the respiratory group. Krog and Dougherty⁷ found *B. coli* in the rinse waters of 19 public bars and taverns. Mallmann and Devereux¹⁰ reported finding streptococci (hemolytic, nonhemolytic and viridans) on used beverage glasses. Organisms

of the respiratory and intestinal groups were found on improperly processed eating utensils at this station. In a preliminary study of the rôle of the tubercle bacillus in dishwashing, conducted at this laboratory, tubercle bacilli were isolated from spoons used by persons with active cases of this disease. In addition to the organisms mentioned, soil bacteria, yeasts and molds and air-borne contaminants are commonly present. The tubercle bacillus and the thermophilic bacteria of the respiratory and intestinal groups are the most resistant to heat of these organisms, the spore bearers excepted. Since heat is the only constant bactericidal agent in machine dishwashing, processing at temperatures and for time periods sufficient to cause thermal death of the tubercle bacillus and the thermophilic bacteria should reduce viable organisms in the wash and rinse waters and on the processed utensils to a minimum. A 60 second wash process at not less than 160° F. followed by a 10 second rinse process at 180° F. was adopted for intermittent single tank machines and a 40 second wash process at not less than 165° F. followed by a 20 second rinse at 180° F. for single and multiple tank conveyor

machines. Tests conducted regularly for over 1 year on all machines showed that utensils processed at these standards were bacteriologically clean. The wash water of an intermittent single tank machine, in the restaurant, after 12 hours of almost continuous use, contained 179 organisms per c.c., of which 23 were non-spore-bearers. The bacteria counts of processed dishes, glasses, and spoons averaged 15 non-spore-bearing organisms per cultured surface. The methods of processing have been carefully checked using a culture of *B. coli* (U. S. P. H. S. strain, regularly reduced 99.99 per cent in 30 seconds at 160° F. in milk or buffered distilled water). Wash tanks of single and multiple machines were seeded with 20 c.c. of an 18 hour broth culture of this organism. Sterile Petri dishes were processed at the standard temperature and time periods. The broth culture was introduced into the wash tank during the first 10 seconds of the wash process in order to simulate the actual detergent action. Immediately following each run samples of the wash and rinse waters were obtained for count and agar poured into the Petri dishes which were incubated for 48 hours at 98° F. A 99.99 reduction of the or-

ganisms seeding the wash tank waters was obtained. Controls were run using the same amount of broth culture at a wash temperature of 100° F. and a rinse temperature of 140° F. The results of these tests are shown in Table V.

Because dishwashing is ordinarily considered a menial task, consisting in the main of tossing utensils haphazardly into a machine containing a solution of a "soap powder," proper administrative supervision is neglected. The evidence presented emphasizes the necessity—from a public health standpoint—of more than merely "washing" utensils.

The term "Pasteurization of Eating Utensils" is used as it is believed that it best described the flash method of thermal destruction of the organisms contaminating used utensils, and conveys to the average mind an accepted standard of cleanliness.

CONCLUSIONS

Soil and bacteria are redeposited upon utensil surfaces during the wash process in single tank machines and during the wash and rinse tank processes in multiple tank machines. Final cleansing is accomplished by the action of the clear water rinse.

The formation of film during processing lowers the efficiency of the wash and rinse operations. Sodium hexametaphosphate by preventing film formation permits free detergent, thermal, and rinse actions.

Thorough scraping of utensils, proper loading, temperature control, mechanical action of wash and rinse sprays, and machine cleanliness are necessary for efficient operation.

Heat is the active bactericidal agent of machine dishwashing. The operation of intermittent single tank machines for a 60 second wash process at not less than 160° F., followed by a 10 second rinse at 180° F. and of multiple tank machines for a 40 second wash process at not less than 165° F., followed by a 20 second rinse at 180° F. results in a 99.99 per cent reduction of the non-spore-bearing organisms contaminating the used utensils.

The Rôle of the Nurse in the Control of Syphilis and Gonorrhea*

GLADYS L. CRAIN, R.N.

*Epidemiologist, Massachusetts Department of Public Health,
Boston, Mass.*

THE control of communicable diseases has long been recognized as a basic public health enterprise for the protection of the community. The results of scientific research and discovery, and the activities of local, state and federal health agencies have been markedly successful in the field of prevention and cure. Many of the common communicable diseases have been practically eliminated and great advances in the management of other plagues of mankind presage their rapid reduction to an irreducible minimum.

No small share of this success has been ascribed to public health nurses. Authorities in public health practice give these workers a recognized place in all plans for community health protection because of their training, their numbers (there are approximately 20,000 public health nurses¹ in the United States), and their ready access to homes everywhere. This relationship with families gives them an unprecedented opportunity to disseminate widely facts which the public needs to know in order to cooperate intelligently with physician and health officer in the broad community health program.

Although nurses have been almost universally employed in general communicable disease work, their usefulness in syphilis and gonorrhea control has been questioned and often entirely ignored; yet these diseases are serious menaces to family health, are communicable, and amenable to treatment and public health management. The fact that they are bound up with personal relationships and the customs and taboos of society has inhibited the professional worker and has been a major factor in their continued prevalence.

It has been shown repeatedly that when the nurse has seen the problems of syphilis and gonorrhea control as an indisputable part of her program the obstacles which loom to insurmountable proportions in theory dwindle in practice to those routine difficulties which complicate all types of individual and family health work.

The attitude of the worker is the foundation upon which accomplishment succeeds or fails. This attitude is fostered by education, and the development of a scientific attitude toward these disease problems. It becomes crystallized as the worker acquires a deep respect for personality, a growing ability to see situations through the eyes of the patient, an aptitude for building on strengths rather than weaknesses, and a profound faith in the powers of persuasive teaching and the

* Read at a Joint Session of the National Society for the Prevention of Blindness and the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

futility of the weapons of fear and force.

It cannot be too strongly emphasized that effective work in syphilis and gonorrhea control requires informed, well trained workers. Education on the job, through institutes, staff education, and summer school courses, must be accepted as a necessity, and improvement and enrichment of courses in training schools should be stimulated.

Happily, the Washington Conference on Venereal Disease Control Work² in December, 1936, made the old controversy regarding the nurse's responsibility in the control of syphilis and gonorrhea a dead issue. The emphasis upon the family aspects of these diseases, especially their disastrous effects upon mothers and children, offered a challenge to all family health workers, and pointed to the potential value of the community nurse as a case finder and case holder.

It is fortunate that the principles underlying the control of the genito-infectious diseases do not differ greatly from those laid down for other communicable diseases. The spread of infection in any case is not checked until the community is protected from the patient himself, the source of his infection, and all those contacts to whom he may have given the disease. All known patients must have continuous treatment until cured, or rendered non-infective, and must avoid activities which will endanger others. Patients must be found and brought to medical care in the earliest stages of the diseases for the sake of community protection and in order that the best possible results may be obtained from treatment.

The program for syphilis and gonorrhea control has been tersely described under 3 heads: (1) education, (2) investigation, and (3) treatment. Such activities as are intrinsic here dovetail

with the recognized functions of the public health nurse whether in industry, private visiting nurse associations, schools, or health department. Educational and investigative technics are part of her stock in trade, and efforts to bring patients early to medical attention and encourage faithfulness to treatment belong to everyday field work routine.

To return to the 3 point program mentioned above, the following come definitely within the province of the nurse:

Education:

1. Assisting with case holding by seizing every opportunity to clarify the situation in which the patient with syphilis or gonorrhea finds himself. This may be an interpretation of diagnosis; an explanation of the reasons for the arduous treatment regime; an exposition of the why's and wherefore's of clinic red tape, or encouragement by re-emphasizing the hope for cure. The control of syphilis or gonorrhea depends, in the last analysis upon a well informed patient.

2. Assisting with general community education by being prepared to give satisfactory information to those who inquire about the diseases, and those who need to be set right regarding fallacies and misunderstandings and unfounded prejudices.

Investigation:

1. Assisting with the tracing of sources of infection. The nurse's knowledge of the families in her bailiwick is intimate. She enjoys the confidence of patients because of her friendly services, and information withheld from others is often hers for the asking.

2. Making arrangements for family contact examinations as she arranges for dental care, tonsillectomies, and a thousand and one other health emergencies.

3. Assisting with the discovery of the unsuspected case by the unflinching recognition of danger signs whether in health histories or the patient himself, and by implanting a desire for medical attention in all who show deviations from accepted health norms.

Treatment:

1. Sharing with patients who need medical attention (but cannot afford private care) a knowledge of hospitals and clinics where free or low-cost treatment may be obtained.

2. Making definite arrangements with such

treatment centers for the admission of patients who need medical examinations or specific treatment.

3. Recognizing other health and social needs in families where syphilis or gonorrhea is present, and through coöperative agency planning, assisting with the removal or alleviation of conditions which hinder effective treatment and efficient living.

Such are a few of the unmistakable ways in which the public health nurse may strengthen the community program for the control of the genitoinfectious diseases.

The community nurse's chief contribution, however, is to that phase of the syphilis program which has to do with the control of syphilis in pregnancy and the prevention of congenital syphilis.

The statements from Dr. Parran's recent book, *Shadow on the Land*,³ should arouse public health nurses to action:

One million potential mothers in the United States now have, or have had, syphilis. . . .

No woman who has had syphilis can be assured that she will not bear a syphilitic child without treatment during pregnancy. . . .

Each year, 60,000 children are born in the United States with congenital syphilis. . . .

Ten times out of eleven, the syphilitic mother will bear a healthy child if treatment is adequate and is begun before the fifth month of pregnancy.

Three times out of five, the syphilitic mother will bear a healthy child if treatment is begun after the fifth month of pregnancy. . . .

Some treatment, any treatment, reduces the risk of congenital syphilis. . . .

Treatment for the control of syphilis in pregnancy has been standardized and outlined in such form that all who run may read. The results of adequate treatment are dramatic. The ultimate eradication of congenital syphilis which is now taking a terrific toll in lives and in human happiness and efficiency is no Utopian dream. The public health nurse might be a powerful force in accomplishing this desired result. No

other worker is as fortunately placed as she, to investigate, to supervise, and to teach, to the end that all pregnant women may seek medical care early and receive the benefits of adequate treatment for themselves and their unborn children if infection is discovered.

It would seem a valuable experiment for organizations to study the possibilities for assisting with the syphilis and gonorrhea control programs in their own communities, and to bring about an alliance of coöperating agencies to this end. It is certain that until a working plan is developed between medical agency, health department, and nursing association, little profit will come from ventures in this field.

There are other realms of usefulness for the nurse in case finding, case holding, and the follow-up of patients who discontinue treatment. These take on the nature of a specialized service, and are particularly appropriate for workers in clinics, the health department, or other agencies which have a measure of responsibility for syphilis and gonorrhea control.

Follow-up, with all its attendant activities, has long been considered the responsibility of medical social service departments where these have existed in hospitals and clinics. In the work with syphilis and gonorrhea patients, however, such follow-up programs have been necessarily restricted, because of ever-widening ramifications and an already overburdened staff. In few instances has the ground been covered adequately from the angle of public health and present epidemiological standards.

In recognition of the need for strengthening the state program at this point, the Massachusetts Department of Public Health has promoted a plan (with the help of Social Security Funds) for supplementing the existing follow-up services in certain hospitals

in Metropolitan Boston, and in other important clinic centers throughout the state. Under this plan, 9 follow-up workers have been added to the staffs of the larger clinics, although all of the 30 clinics in the state already had basic follow-up services. The state coöperates by making funds available to each clinic to cover salary, clerical assistance, and travel expenses of the new personnel, but assumes no administrative or appointive responsibility.

These workers are public health nurses in the majority of instances, although social workers are also employed. The public health focus is essential to the success of the program. The workers must not lose sight of the importance of mass achievement as distinguished from too much individual effort upon patients who present long-time problems. All complicated case work situations are referred to the hospital social service departments for solution, since rehabilitation of patients and families is as necessary to community well-being as the emergency measures of public health control.

The standard procedure for the follow-up workers includes the immediate investigation of certain classes of patients in the order listed below:

1. Patients who have discontinued treatment for early (primary or secondary) syphilis
2. Identifiable contacts of such patients
3. The pregnant woman with syphilis
4. The infant with acute congenital syphilis, or the child with interstitial keratitis
5. Patients who have lapsed treatment for gonorrhea
6. Identifiable contacts of such patients
7. Familial syphilis in any stage not included in above
8. Patients with late syphilis

Although these workers are doing the emergency follow-up, their approach to patients is not perfunctory. They definitely strengthen case holding in the clinic by re-interpreting diagnosis, by explaining the mystifying or unfor-

tunate happenings in the hospital, which may have discouraged the patient, and especially by making sure that the patient's reinstatement in the clinic will be consummated without annoying accidents.

One of the tragedies of follow-up is to convince a patient of the importance of continuing treatment, and to have him subsequently met at the clinic door by a cold rebuff. Such a person is frequently lost to clinic influence thereafter.

Let it be understood that the patients visited by the workers in the Massachusetts project represent the more difficult group who fail to respond to hospital follow-up letters. Formerly, such patients would have been reported to local health departments as recalcitrant. The advantage of the present type of follow-up is that the worker represents the clinic which the patient is attending and not the board of health. Thus, the patient is not antagonized by implications of delinquency on his part and is reassured regarding the interest of the clinic, and the confidential nature of its services. The success of the new work is shown in an increase in clinic attendance, and a declining number of uncoöperative patients on the books of the local boards of health.

From January 1, 1937, to July 1, 1937, rough estimates⁴ indicate that 2,462 cases of syphilis and gonorrhea have had follow-up visits. Of these, approximately 68 per cent, or 1,683 patients, have been successfully brought back to treatment, or persuaded to seek medical advice. This is an encouraging accomplishment when compared with the best figures obtainable for board of health follow-up. In a 6 year period, 43 per cent of 20,000 patients were found, but there is no information available as to how many actually returned to treatment.

Cases which failed to respond to this new type of follow-up numbered 779, or about 32 per cent. In one district, largely residential, 80 per cent of the patients responded satisfactorily. The congested sections of cities presented the more difficult problems. It would be folly to intimate that such estimates could accurately measure qualitative results. They are but straws in the wind. The program is still experimental, and only a superficial study of figures has been possible thus far. As the work progresses and technics improve, better results are certain (see Table I).

A capacity to learn out of failures as well as successes is a necessary attribute of these workers. Such continuous and serious efforts on the part of the nurses and social workers will at long last bring a definite and demonstrable halt in the spread of the genitoinfectious diseases.

A like service is being offered to private physicians who are shouldering a greater burden than the clinics. The problem has been how to reach this group. The traditional personal and confidential relationship of physician to patient makes for reluctance on the part of the physician to accept help from outside organizations—particularly, the state! During the past year, the department has begun experiments with a confidential serv-

ice. A public health nurse is loaned (on a time basis) to physicians who desire assistance in the follow-up of lapsed cases or contact tracing. The nurse becomes the physician's nurse the moment she enters his office, and at no time does she represent the Department of Health. All identifying data regarding the patient is kept strictly private and is not available for state records. The department has no part in the procedure beyond receiving statistical data and providing personnel.

Of the doctors visited thus far, only a negligible group has failed to avail itself of the service. The program has been too limited up to the present time to quote statistics, but it can be stated that the majority of cases which discontinued treatment or were exposed to infection have been closed to medical care to the satisfaction of physician and patient. There has been nothing to disturb the patient's faith in the physician's interest in him as a person, and in his sincere desire to keep the patient's confidences inviolate.

Public health nursing organizations frequently complain of their inability to carry on any kind of program in syphilis and gonorrhea control work because of the lack of coöperation by the local doctors. Might it not be worth while to experiment with such a scheme as this and build up a new relationship? Loaning nurses on a

TABLE I
RESULTS OF FOLLOW-UP
JANUARY 1, 1937-JULY 1, 1937
*Massachusetts State Project for Supplementing Existing
Epidemiological Services*

Disease	Cases Referred	Visits Made	Results	
			Cases Returned to Treatment	Failures
Syphilis	1,858	3,032	1,335	523
Gonorrhea	528	774	301	227
Undiagnosed	76	126	47	29
Totals	2,462	3,932	1,683	779

time basis to clinics is a widespread practice—why not to the private physician?

Studies of the incidence of syphilis and gonorrhea show that the peak of prevalence of these diseases is found in the age group of 15 to 30 years. This fact should have significance for the public health nurse in industry and in the schools. The tremendous possibilities for educative procedures and for case finding in these situations is only just beginning to be recognized.

CONCLUSIONS

1. Public health nurses in schools, industrial plants, health departments, clinics, and visiting nursing organizations have a definite contribution to make to the control of syphilis and gonorrhea.

2. Provision should be made for acquainting agencies which employ nurses of their opportunities to assist in the control program.

3. Provision should be made for acquainting clinics, private physicians, and health officers with the work which nurses are qualified to do in case finding and follow-up.

4. Provision should be made for the continuous education of the public health nurse in the medical, public health, and social aspects of syphilis and gonorrhea control.

5. Studies should be made of local community needs, and appropriate contributions of the nurse in different types of agencies. Experiments in this field should be evaluated from qualitative and quantitative standpoints.

Syphilis and gonorrhea are major public health problems today, and they are amenable to public health control. There are 20,000 public health nurses in the country. Is it not imperative that the skills of this group be enlisted in the nation-wide campaign which was initiated last December?

Cemeteries or Playing Fields?

... When speaking at the International Cremation Congress last month, Lord Horder described burial as a luxury we could no longer afford. Land was needed for building and for the recreation of the people: to continue the uneconomic use of land for the wasteful purpose of burial would be criminal in the face of the social needs of the population. Already most civic

authorities were despairing of finding fresh acres for cemetery purposes and were turning to cremation as a means of preserving the land in the interests of the living. Cemeteries or playing fields? That was the question, and from an educated community there could be only one reply.—*J. Roy. Inst. Pub. Health & Hyg.*, 1, 2 (Nov.), 1937.

A Suggested Program of Control of Amebiasis by Health Departments*

CHARLES F. CRAIG, M.D., F.A.P.H.A.

Colonel, U. S. Army (Retired); Department of Tropical Medicine,
School of Medicine, Tulane University, New Orleans, La.

THAT infection with *Endamoeba histolytica*, or amebiasis, which includes amebic dysentery, is a public health problem in this country is slowly but surely becoming recognized, and it is greatly to the credit of the Mississippi Public Health Association, and of the State Board of Health of Mississippi, that amebiasis has been so recognized for several years and that measures to combat it and to secure reliable data as to its incidence have been pursued by the State Board of Health. This has resulted in more accurate statistics as to the incidence of this infection and, in fact, Mississippi stands almost alone among the states of the Union in possessing any really reliable statistics concerning amebiasis. As I stated in my Presidential Address before the American Academy of Tropical Medicine, in 1936:

The only state which is apparently "amebiasis-conscious" is Mississippi, for in 1932 the State Board of Health reports 481 cases of amebiasis. Whether these were all cases of amebic dysentery, or not, we have been unable to learn, but probably not. At any rate, the State Board of Health in Mississippi is apparently succeeding in obtaining much more accurate information regarding the incidence of amebiasis in that state than in any other state considered in the Survey.

In order to establish the fact that amebiasis is really a public health problem in this country it is necessary to prove that *Endamoeba histolytica*, the cause of this infection, is a pathogenic parasite; that it is present in a significant proportion of the population; and that its presence endangers the health of the individual harboring it. All of these postulates have been fully demonstrated. There is no doubt regarding the pathogenicity of the parasite; the evidence is conclusive that approximately 10 per cent of the population of the United States harbor this parasite; and that at least 50 per cent of individuals harboring it present symptoms caused by it; and that, even in those who present no symptoms, there is tissue invasion, and symptoms may develop at any time, or an amebic abscess of the liver may occur in symptomless individuals. In view of these facts it must be admitted that amebiasis is a real public health problem in the United States and deserves careful consideration by all health departments in regions where infections with *E. histolytica* are known to be present in significant numbers.

Owing to the comparatively large number of individuals that have been found infected in many localities: the difficulty of diagnosing the condition, which must depend upon demonstrating the parasite; and the expense involved in examination and treatment: the pre-

* Presented before the Mississippi Public Health Association at Jackson, Miss., December 9, 1937.

vention of amebiasis is a very complex problem and one that must be handled variously in different localities and under different conditions.

We know that the cysts of *E. histolytica*, the usual transmitting agents, may be transmitted from man to man through a contaminated water supply, either public or private; through the ingestion of contaminated food or drink, such contamination usually being due to infected food handlers; through flies that have fed upon contaminated material and, in turn, have contaminated food or drink by contact or by their droppings; and through the use of human excrement in the fertilization of garden products. Any program looking toward the control of amebiasis must embrace all of these methods of possible transmission and, fortunately most of them can be controlled without undue expense or labor.

As the recognition of *E. histolytica* is absolutely essential before a diagnosis of amebiasis is possible, the first step in the control of this condition consists in the training of physicians and laboratory technicians in the differentiation of this species of pathogenic ameba from the four other species living in the human intestine, all of which are nonpathogenic, so far as known. I believe that the difficulty of differentiating *E. histolytica* from these other amebae has probably been exaggerated, but it is true that one must have considerable experience in the study of the parasitic protozoa of the intestine in order to make the differentiation. It is believed, however, that any well trained laboratory technician or physician trained in the use of the microscope should be able to differentiate this ameba after several days of personal instruction by a qualified instructor and from 5 to 6 weeks' practice in the microscopical examination of the feces and a careful study of the amebae present. Staining methods are also

available that make the recognition of *E. histolytica* a matter of little difficulty after one has been properly instructed in their use and in the morphology of the ameba when stained by these methods.

The first step, then, in a program for the control of amebiasis, is the training of a sufficient number of laboratory workers so that they may be available for the examination of material in regions where the infection is prevalent. Such trained technicians should certainly be available in all city, county, and state health laboratories, and to these laboratories should be forwarded specimens for examination obtained during surveys or from the practicing physician. Unless such trained laboratory technicians or physicians are available it would be foolish to undertake any control procedures as we would not know whether or not control measures were necessary in any given locality.

The next important essential in the control of amebiasis is to make this infection a notifiable disease, and in doing so, that the physician be thoroughly acquainted with what is meant by the term "amebiasis." By the term "amebiasis" is meant infection of man with *E. histolytica* without regard to the presence or absence of symptoms of such infection. The term includes cases of amebic dysentery, or diarrhea; of amebic abscess of the liver or other organs; of gastrointestinal symptomatology other than diarrhea or dysentery, and it also includes all individuals presenting the organism in their stools but who have no symptoms of the infection, the so-called "carriers" of *E. histolytica*.

In selecting a nomenclature that would be satisfactory in reporting cases of amebiasis, that recommended in the *Standard Classified Nomenclature of Disease* is considered admirable for the purpose. Under the general term

"Amebiasis" is included amebic infection of any organ of the body, the organ being specified, while separate designations are provided as follows: amebic abscess of brain, liver, or lung; amebic colitis; amebic hepatitis; amebic proctitis; *Amebiasis cutis*; and amebic carrier state. In reporting cases of amebiasis these terms should be employed, if possible, and amebic infection elsewhere in the body than indicated by these terms should be reported as amebiasis, signifying the site of the infection.

It is unnecessary to state that unless amebiasis and its complications are made reportable conditions any system of control of this infection is impossible, and it is certainly true that the lack of such a requirement is responsible for much of our ignorance of the extent and importance of the infection. I believe that if all cases of amebiasis now being diagnosed in this country were reported we would be greatly surprised at their number and importance, from the standpoint of the health of our people, especially in the southern states.

The control of amebiasis can be greatly assisted by the education of the public regarding the importance of this infection and the methods of transmission, as well as those which have been found effective in preventing transmission. Public education is an important part of the program of control, and this is ideally accomplished through publications issued by local or state boards of health. Such publications should include the statement that amebiasis, including amebic dysentery, is not a tropical infection, as is generally believed, but is very prevalent in this country and that, even though symptoms of the infection may not be present, grave complications, as amebic abscess of the liver, may occur. The part played in transmission by symptomless carriers of the infection should be stressed, and the simple hy-

gienic rules which serve to prevent such transmission should be emphasized. The importance of the food handler, either in the home or in public eating places, in the transmission of this infection should be explained, and the fact that if one member of a family is found infected with *E. histolytica* other members are also apt to be infected. Personal hygiene as a valuable prophylactic method should be emphasized and the great importance of a thorough cleaning of the hands before handling food or eating, as well as after the use of the toilet, should be emphasized. It should be stressed that if these very simple hygienic rules were strictly observed by all who handle food, amebiasis would probably cease to be a public health problem in well sanitized localities, as our larger cities and towns. The public should be informed that amebiasis is a strictly preventable infection and it is believed that the education of the public regarding it is a most valuable part of any program looking toward the control of the infection.

In view of the experience gained in the study of the extensive epidemic of amebic dysentery which occurred in Chicago, in which cross-connections between the sewer and the water supply of the hotels concerned was determined as the source of the infection, the inspection of the plumbing of public buildings and hotels becomes a part of a program for the control of amebiasis. Such inspections should be made by properly trained sanitary engineers (as it is often difficult to locate such cross-connection), and should not be trusted to the usual sanitary inspector unless he has been well trained in sanitary plumbing. Just how frequently amebiasis is transmitted in this manner is unknown, but the program of control should include such inspections and the laws prohibiting such cross-connections should be rigidly enforced.

The protection and sterilization of water supplies are important parts of a control program for this infection. It has invariably been noted that, in regions where amebiasis was frequently encountered, the installation of a properly constructed and guarded water supply system has been followed by a great decrease in the number of infections with *E. histolytica*. Water is of little importance as a transmitting agent in towns or cities having such a supply, except in instances such as occurred in Chicago, where a cross-connection between the supply and a sewer caused an epidemic of amebic dysentery. Filtration through filter beds removes the cysts of this ameba and renders the water safe so far as transmission is concerned. In rural districts, however, where families depend for their water supply upon wells, springs, or streams, and where sewage contamination is possible, such water may transmit the infection through the cysts being washed into the source of the supply, and the control of such conditions becomes a part of a control program.

The proper disposal of human feces is also an important part of a control program and should be carefully investigated in regions where amebiasis is common. The laws forbidding the use of human excrement for the fertilization of vegetable gardens should be strictly enforced, and if such laws do not exist they should be enacted and enforced. The use of the sanitary privy is just as important in the control of amebiasis in rural communities as in the control of hookworm or other parasitic infections, and the enforcement of laws or regulations regarding the sanitary privy and those forbidding indiscriminate defecation in the vicinity of human habitations, or near possible sources of a water supply, becomes a necessary and important part of a control program for amebiasis.

The prevention of fly breeding and the protection of food from flies should likewise form a part of the control program. It has been demonstrated beyond question that the cysts of *E. histolytica* may live in the intestinal tract of the fly for as long as 48 hours and that during this time the excrement of the fly contains viable cysts which may be deposited upon food, thus contaminating it and spreading amebic infection. In addition, flies may carry viable cysts of the ameba upon their feet and thus contaminate food should they walk over it in feeding. Cockroaches have also been found capable of transmitting the infection.

The detection of infected food handlers should form a part of any program for the control of amebic infection. Efforts have been made in some quarters to belittle the importance of infected food handlers in the transmission of amebiasis, but the fact remains that it is impossible to explain the transmission and the persistence of this infection in well sanitized districts in any other way, while the frequency with which familial infections with this parasite occur, in which the cook or other person preparing and handling the food for the family has been found to be a carrier, adds to the evidence of the importance of this method of transmission. Where there is an impounded, filtered water supply, where sewage is properly disposed, and where sanitary plumbing exists, the transmission of amebiasis must be almost entirely due to contamination of food and drink by food handlers infected with *E. histolytica*. If this were not true amebiasis would long ago have disappeared from our towns and cities.

It has been urged that the examination of food handlers for this parasite is not practicable because of the number of such individuals and the expense involved. It is very easy to recommend that all food handlers in our pub-

lic eating places and hotels be examined and those found infected with *E. histolytica* isolated and properly treated, but when one considers what is involved in such a recommendation when applied to a large city, it must be admitted that, while ideal, such a procedure would not be possible owing to the time involved; the great expense attending the examination and the treatment of the infected; and the loss of time and money to the infected individual and his employer. While all this is true, the examination of food handlers is practicable in many localities, owing to the small numbers involved, and certainly in our smaller villages and towns, it is feasible to examine all the food handlers in public eating places for this infection and to eliminate their infection by proper treatment. While it is best to forbid infected food handlers to pursue their occupation until their infections are eliminated, this is not absolutely essential, for the food handler may be given treatment while still pursuing his occupation, and he can be warned that he is a danger to others and instructed as to the precautions he may take which will prevent the transmission of amebiasis by himself while he is undergoing treatment. Likewise, if a case of amebiasis is discovered in a family, it is perfectly feasible to examine the other members of the family and, if any are found infected, to treat them. Certainly the control of amebiasis will be greatly assisted if as much as is possible is done in the way of the examination of food handlers and the treatment of those found infected.

The detection of carriers of *E. histolytica*, aside from those handling food should be included in a program for the control of amebiasis and as much should be accomplished along this line of attack as is possible. Owing to their great number it is obviously impossible to detect all carriers, as this

would entail the examination of the entire population of the country, but the laboratory examination of the feces of all individuals in families in which one member has been found infected, and of as many as possible of the population in localities where amebiasis is frequently encountered, or where numerous acute amebic infections are occurring, should be attempted by the health authorities. When funds and trained personnel are available surveys should be conducted to determine the incidence of amebic infection in regions where such infection is known to occur, or in other regions where it probably occurs, and infected individuals should be treated and instructed regarding the nature of the infection and the methods of transmission. The inmates of public institutions, such as hospitals, orphan asylums, insane asylums, etc., should be examined, as in such institutions the incidence of infection with *E. histolytica* is frequently excessive, especially in insane asylums.

What may be accomplished in the examination of a population for infection with *E. histolytica* is well illustrated by the results obtained by Seckinger (1936) who, in villages in rural Georgia, examined the members of 69 families, including 290 individuals, and found 162, or 55.09 per cent, infected. In several families the infection rate was found to be as high as 90 per cent, and in one family of 11 members, 10 were found positive. Of these, 1 suffered from dysentery at the time of examination, in 5 others symptoms of amebiasis were present, while in 4 there were no symptoms or history of symptoms.

I have endeavored to outline briefly the measures that should be included in a program for the control of amebiasis. The administrative details connected with such a program must, of course, be worked out by the city, county, and state health boards of the states in

which such a program is adopted; but it is believed that if proper coöperation is obtained between the organizations concerned, a program for the control of this infection is feasible and could be conducted without too great an expenditure of money.

Summarizing what should be included in a program for the control of amebiasis by health departments, such a program should include the following, to be participated in by city, county, and state health departments as the situation indicates:

1. Making amebiasis a reportable condition, using a nomenclature for reporting it similar to the one now recommended in the *Standard Classified Nomenclature of Disease*.

2. The training of a sufficient number of health laboratory workers in the recognition of *Endamoeba histolytica*, the cause of this infection.

3. The education of the public regarding the infection and its importance as a public health problem, by means of printed information, radio talks, etc.

4. A careful inspection of public buildings, hotels, restaurants, and other public eating places as to the presence of possible cross-connections in the plumbing system between sewers and the water supply.

5. The protection and sterilization of water supplies in rural districts and villages or towns where an impounded and filtered water supply is not available.

6. The proper disposal of human feces, and the enforcement of regulations regarding this matter.

7. The examination of food handlers for the detection of infected individuals and their proper treatment after detection, in so far as is possible with the facilities at hand.

8. The detection of carriers of *E. histolytica* by means of surveys of the population in localities where epidemics of amebiasis may occur or where it is believed that such infection is responsible for illness.

9. The prevention of fly breeding, and the protection of food and drink from flies and other insects, such as cockroaches.

Fortunately, most of the items included in this program are already taken care of by present regulations of our city, county, and state boards of health, and all that is needed is to enforce such regulations; but much remains to be done, so far as the control of amebiasis is concerned, in training personnel in the recognition of *E. histolytica*; in educating the public regarding the importance to health of infection with this parasite; and in the examination of food handlers and other individuals in localities where infection is known to exist or in others where it is suspected of being present. These are the most important parts of a control program and until something is done about them amebiasis will continue to be a public health menace in the United States.

National Health Survey

THE Division of Public Health Methods of the National Institute of Health, U. S. Public Health Service, Washington, D. C., released on January 17 preliminary reports of the National Health Survey of 1935-1936.

Bulletin No. 3 describes the findings regarding illness and medical care in relation to economic status.

This comprehensive survey was conducted by the U. S. Public Health

Service with the aid of financial grants from the WPA. These findings are based on a house-to-house canvass of some 800,000 families, including 2,800,000 persons in 84 cities and 23 rural areas of 19 states. The survey was made during the winter of 1935-1936, and the total survey population was so distributed as to give a sample representative of cities in the United States according to size and region.

PUBLIC HEALTH EXPANDING

ONE does not have to watch the literature too attentively to discern a growing interest in public health and to detect the recognition by the profession that preventive medicine and public health are expanding—that constantly new items are entering into the practical field, and from the very nature of things are demanding more and more attention. For many years, and too much so even today, public health in the mind of the average person has been considered as referring chiefly to the infectious and contagious diseases. The medical profession has not yet gotten away from this idea entirely. It is true that even now this group of diseases causes more than half of all deaths and probably even a higher proportion of illness. We are constantly achieving triumphs in the prevention of preventable diseases the cause and manner of spread of which we know. We are even from the practical standpoint improving the outlook of certain other diseases; cancer for example, the cause of which we do not know, and which is certainly not contagious in the ordinary sense of the term.

Mental Hygiene—For several years we have had a group in our Association interested in mental hygiene, and some excellent papers have been given, most of which have found their way into our *Journal*. At our recent meeting the importance of this subject was stressed, and one thoughtful paper expressed the opinion that there was a distinct epidemiology of mental disease; another held it was a function of health departments; another spoke of the training of nurses in order to help mothers in the prevention of mental twists; while a fourth spoke of the achievements and possibilities. There can be no question of the importance of this subject. Since 1910 there has been an increase of 122 per cent in the number of patients in mental hospitals, although the population of the country during that time has grown only 40 per cent. Some of this increase in the number of patients is due to better facilities, to a partial overcoming of the idea that mental trouble is a disgrace, but there is some indication also that the actual number of mental cases is increasing.

The first child guidance clinic in this country was established in 1909, but for children and adults there are now 683 such clinics in the United States, and 53 in Canada, serving more than 12,000 new cases annually. So far it is difficult to evaluate the preventive effect of these clinics, but there is some evidence that they are doing much good.

During the past 6 years, some 36 medical schools in this country and Canada have introduced or improved their facilities for clinical instruction in psychiatry, the recognition of a need which was introduced to us largely less than 30 years ago, although insanity and other types of mental trouble have been with us throughout all time.

Accidents—Perhaps the next most urgent demand for consideration as belonging to public health is the matter of accidents, which have been grouped under the title, "External Causes of Death" in the *International List*. Such a prominent place has been taken by automobile accidents that most of us have almost forgotten that there are other causes of accidental death. For 1937, the number of deaths from automobile accidents is computed at approximately 37,000 and the number of injuries more or less severe at about one and a quarter million. For the last year in which we have accurate statistics, the death rate was 24,500 for persons 15-64 years of age, and 4,300 for children under 15. It is well said that "This wholesale slaughter is without parallel outside of America." America, of course, leads in this slaughter. Many factors are concerned in this question; mental capacity, habits, the use of alcohol, etc. Whether we wish it or not, the matter has been forced upon us as a public health problem.

On the other hand, railroad accidents have decreased and, as far as passengers are concerned, have almost vanished. Too many employees still meet with accidents and death. Indeed, some of the accidents such as those at grade crossings, for example, are generally due to the drivers of automobiles.

Suicide—Every year some 20,000 people in the United States commit suicide, meaning that of every 1,000 white males born, 18 will sooner or later take their own lives, against 5 for females. Again, many factors come in here, some of which belong distinctly under the public health aspects of mental hygiene. As Dublin and Lotka¹ express it, "Suicide is indicative of a badly integrated personality . . . the end result of personal maladjustment and frustration which can often be avoided were the individual in question helped, before it is too late, to solve his conflicts in a more constructive fashion."

Homicide is another cause of death which does not exercise us as a public health matter as much as it should. In a paper read before our Annual Meeting,² on October 6, 1937, it was clearly said, "Homicide is a preventable cause of death."

Space does not permit a discussion of the various other types of accidental death, such as falls, burns, firearms, mining, machines, electricity, poisonous gas, etc. It must be clearly pointed out, however, that all of these deeply concern the vital statistician, and vital statistics is the bookkeeping of public health. It is impossible to avoid the conclusion that some, if not all, of these matters deserve inclusion under the general title of public health.

Cancer—Cancer is definitely not contagious or infectious in the ordinary sense of these terms, yet it has always been a question which loomed large, and of necessity has engaged the attention of public health workers. Its apparent increase has led to considerable discussion. With the prolongation of the span

of life which has taken place chiefly through preventive measures in the early years, more people are reaching the age when cancer becomes more prevalent. From every standpoint cancer deserves to be considered a public health problem. While it is true that a large and well managed journal is devoted to this subject, and that there are a number of Funds devoted to the study of cancer from every aspect, the Annual Meetings of this Association should have more papers on cancer, discussing the advances made, our knowledge of it, and its prevention by such measures as are known to be effective.

Diabetes is another disease which is not contagious. It is attracting more attention each year, and papers have been given to us concerning it, one of which is now in preparation for publication.

Housing and Nutrition—In our sister country, England, housing and nutrition appear to be the two matters which are attracting the most attention. Both of them have unquestionably a tremendous effect upon the health of the public, to say nothing of our general well-being and efficiency. At our recent meeting, a symposium was presented on the Hygiene of Housing, which included, of course, heating, ventilation, lighting, etc. This will be published in the March issue. We can remember when the matter was taken up in this country largely by Mr. Veiller, in connection with tuberculosis, and a clear demonstration was given, especially for New York, of the bad effects of the tenement house system as it then existed, on the incidence of tuberculosis. Heating and ventilation engineers and architects have perforce continued some excellent studies, but discussions of these matters as public health problems have not been as active as they should have been.

This discussion has taken into consideration what seemed to be the most immediate and most urgent needs. Others could well be added. Several diseases which interest the vital statistician and the health officer and which have been in the past considered as non-contagious are now believed to be partly or in whole caused or aggravated by certain infections, obscure or otherwise.

The list of items heretofore and at present included under the general term of public health, has grown and must grow. The term might well be expanded to include all causes of disability and death other than those generally called—often mistakenly so—natural causes. Our Association has expanded from a comparatively small group made up of medical officers of health into an organization which now has 10 sections, with several others clamoring for admission. We believe that our organization must expand and that our official organ, the *American Journal of Public Health*, will have to expand along with the Association and the demands upon it.

AIR-BORNE INFECTION

IN the early days of bacteriology the air was regarded as being a frequent vehicle for carrying infection. As early as 1861, Pasteur demonstrated the presence of microorganisms in the air of various places, the number varying with the locality. Experiments were carried on by Lister, Tyndall, Miquel, and

others, and many will remember that one of the first publications on bacteriology in America was "Dust and Its Dangers." Lister guarded against the suspected dangers of air by operating under an antiseptic spray and covering the wound, after operation, with many layers of dressings. It was not very long, however, before experiments indicated that the air played a minor part in the infection of wounds, and attention was turned to cleanliness, sterilization, and antiseptics.

Nearly 25 years after the experiments of Lister and 10 years after those of Tyndall, Flügge, having failed to recover organisms from the mouth and nose on plates more than a few feet from the faces of persons coughing and sneezing, advanced the theory of "droplet infection." Observations such as those made at the Hospital of the Pasteur Institute, the Hôpital des Enfants Malades, and by Grancher, all in Paris, seemed to prove that infection through the air occurred in a minimum percentage of cases.* Belief in air-borne infection became practically eliminated, though there were always certain diseases, notably smallpox, measles, and influenza, that did not seem to fit into the prevailing ideas. Such terms as "volatile" and "diffusible" were applied to some viruses.

Articles on the subject appeared fairly often and experiments were carried on, especially concerning the possibility of the air-borne transmission of tuberculosis. Guinea pigs placed in the ventilating shafts of hospitals for consumptives became infected in some instances, but even when these animals were injected with dust collected in such shafts, positive results were surprisingly few (2.7 per cent of 74, London Hospital for Diseases of the Chest, Heron; 1 of 16, from a military hospital, Kirchner). Flügge had entirely negative results in experiments on guinea pigs exposed to the inhalation of such dust. Cornet, 1899, excited much interest when he demonstrated tubercle bacilli in dust from hospitals and private houses in which there were phthisical persons, and succeeded in infecting 46 of 48 guinea pigs by exposing them to dust grossly polluted with dried tuberculous sputum.

Again more than 25 years passed without very active studies of the question. Interest in the matter has been revived and a number of recent investigations have shown the existence of specific germs in the air of hospital wards. For example, the air in four scarlet fever wards was found to be heavily infected with the *Streptococcus pyogenes*, and in one the types corresponded to those found in the patients. The organisms were widely spread and the types identified were often found away from the vicinity of patients infected with these particular types.¹ At the National Institute of Health, psittacosis virus was apparently conveyed by the air from the basement to the upper floors.²

For some 5 years, studies on air-borne infection have been going on at Harvard.³ New methods and new apparatus have been designed.⁴ It has been shown that the droplets described by Flügge do not necessarily fall to the ground within a short distance. As their size becomes smaller by evaporation they fall more and more slowly, and finally become so minute that their behavior in air is comparable to particles of smoke rather than to the droplets described by

* At the Hospital of the Pasteur Institute the wards open into a common corridor. In $2\frac{1}{2}$ years 2,000 patients were treated, including 524 cases of smallpox, 443 diphtheria, 126 measles, 163 erysipelas, 92 scarlet fever, 166 non-diphtheritic sore throat. There were 6 cross-infections—4 smallpox and 2 erysipelas.

At the Hôpital des Enfants Malades the beds are separated by partitions. With 5,017 patients there were 7 cross-infections—6 measles and 1 diphtheria.

Grancher has two wards with no partitions, only wire screens as reminders to the nurses. In 10 years he had 115 cross-infections of measles—7 of scarlet fever and 1 diphtheria.

Flügge. In experimental apparatus it has been shown that they persist in diminishing numbers for hours and even days. The dried residues of these infected droplets, called "droplet nuclei," remain suspended for a long time, and may be carried long distances from their source. Droplet infection is essentially localized and concentrated, but that by droplet nuclei is more dispersed and dilute.

The viability of a number of the germs contained in these droplet nuclei has been determined. Generally speaking, 4 organisms characteristic of the upper respiratory tract—pneumococcus type I, *B. diphtheriae*, *Streptococcus haemolyticus* and *Streptococcus viridans*, are found decidedly more viable than the intestinal group of organisms, having been recovered after 2 days. Experimentally, *B. coli* put into the water of a 1 room air conditioner in the basement of the Harvard School of Public Health, which does not have mechanical ventilation, was recovered from the ends of every corridor of a 3 story building, showing that infected droplet nuclei can be dispersed by ventilating currents throughout a building.

The expulsion of infected droplet nuclei by sneezing has also been proved. Bacterial samples collected in the centrifuge³ on blood agar tubes showed thousands of alpha streptococci and *M. catarrhalis*. It is well known that the diseases spread by the upper respiratory tract and taken into the body through the same tract are those hardest to control. In 1933 more than 85 per cent of the deaths from infection and parasitic diseases in the United States were from diseases in which the usual portal of entry is the nasopharynx, and in the same year the incidence of measles was the highest of all diseases, while influenza came next. It is generally admitted that nasopharyngeal infection is practically universal.

Those who carried out the studies mentioned hold that the burden of proof of air-borne infection, which has until this time rested on bacteriology, has been lifted, and it is now necessary for epidemiology to disprove the fact of air-borne diseases.

It is evident that a reëxamination of some of our beliefs is necessary. It remains true that direct evidence of air-borne infection is, on the whole, lacking except in special cases. Without questioning the experimental data brought forward, which we believe to be of great importance, it seems that infection resulting in clinical disease would be more widely spread than is apparent. In 1918-1919, during the pandemic of influenza, one of the most contagious diseases, the percentage of the population affected was relatively small (11 per cent).

The experience of the English with "bed-isolation" wards indicates that they are as effective as cubicle isolation. In these wards a variety of diseases are treated side by side, though acute cases are separated by at least 12 feet, and strict "surgical asepsis" is insisted on. In the British Navy good results are believed to have been obtained in checking infection in meningitis by making the men lie alternately head to feet. Such facts point to the importance of direct contact rather than to the air as a vehicle.

Further investigation of this important problem will be welcome.

DR. LAWRASON BROWN

THE death of Lawrason Brown on December 26, 1937, deserves more than passing notice. He was a Life Member and Fellow of this Association. Breaking down with tuberculosis when he was a medical student at Johns Hopkins Medical School, he spent most of the rest of his life at Saranac Lake where he was a student and assistant under the late Dr. Edward Trudeau.

He was a member of many learned societies. His bibliography was extensive, but perhaps his chief contribution was to *Osler's Modern Medicine*. Indeed, when this book was projected the publishers made a stipulation that the chapters on tuberculosis should be written by the men at Saranac Lake.

In addition to his specialty, Dr. Brown took a great deal of interest in public health generally, concerning himself over pure milk for his community, and if the writer's memory is correct, served for several years as Health Officer of Saranac. This *Journal* is indebted to him for a number of masterly reviews of books on tuberculosis. He had not only excellent training, but rare good judgment, and his judgment of books was sound always.

His personal character was most attractive. No one knows the many kindnesses he did more or less secretly, in which he followed the lead of the founder of Saranac Sanatorium, Dr. Edward Trudeau, who at the end of a day had often given away more money to patients than he had taken in. It is needless to add that Dr. Brown had hosts of friends in this country as well as in Europe who will mourn his loss not only personally, but as a master in his knowledge of tuberculosis. We extend to his wife and family our most heartfelt sympathy.

JOURNAL POLICY

IT is good business for an organization to take stock of itself now and then, especially a successful organization with no urgent reason for so doing. A degree of success sometimes acts as a sedative to initiative, instead of energizing directors and staff to greater aggressiveness and progress. When that happens the policy of *laissez faire* prevails, former perception of opportunities for expansion and profit, whether financial or professional, is dulled and eventually retrogression begins.

This philosophy of critical examination and appraisal of basic structure, of objectives, of enterprises and services, has served the American Public Health Association well. The attitude of its governing boards and of its members has always been that of a father of our acquaintance who examines the scholastic record of his honor-roll child every month with the comment, "Very good, but room for improvement." Such an attitude implies always that the ability to do better exists and that a little harder work, a bit more thought, a slight shift in emphasis will assure another advance.

Stock-taking of the standing committee organization of the Association last year led to the conclusion that, effective as the five committees had been, administration would be simplified if two—Fellowship and Membership, and Meetings and Publications—were dissolved. Accordingly, these committees were abolished and most of their responsibilities were centralized in the executive office. Celerity of decision and smoothness of operation have been immediate results. Two major duties of these committees required more formal treatment. The pre-

liminary passing upon qualifications of applicants for membership and fellowship, formerly the authority of the Committee on Fellowship and Membership, was placed in the hands of a new standing Committee on Eligibility. The *American Journal of Public Health*, previously under the jurisdiction of the Committee on Meetings and Publications, will in future be directed by an Editorial Board especially created for the purpose. Dr. Mazÿck P. Ravenel continues as Editor.

The *American Journal of Public Health* is a going concern. Under the editorship of the past fifteen years, it has shown a steady and healthy growth. It is regularly abstracted in the leading health journals in Europe and America. The circulation of this issue is the largest in its history—close to 8,000. There can be nothing very wrong with a magazine that holds its readers year after year and adds consistently to its circulation. Sustained reader-interest, to use the expression of the circulation manager, bestows the accolade of approval on any periodical, without benefit of scroll or testimonial. And sustained reader-interest is measured by nothing under the sun but a straight numerical count of subscription renewals. The *Journal's* record in this connection is the envy of more than one publisher we know.

The Editor, the Executive Board, the business office do not want to stand on records, however. "Very good, but room for improvement." Therefore, when the organization stock-taking made necessary a different division of publication responsibilities, it was welcomed as an opportunity to check up again on *Journal* direction and scope to make sure that no possibilities for usefulness to the public health profession were being overlooked. The Editorial Board had served long and well, but its 15 members were scattered geographically, making anything but communication by mail out of the question except at rare intervals. Some of the Editor's tasks were tedious, added to him by accretion rather than by purpose. Finally, after weeks of discussion, in which all concerned participated, a plan emerged which promises to be generally satisfactory. It involves an Editorial Board of five, all within easy access of the executive office, and consequently available for frequent consultation individually and collectively. The Chairman is the Executive Secretary, who also serves as Managing Editor, and the other members are: Prof. Ira V. Hiscock, Kenneth F. Maxcy, M.D., Arthur P. Miller, C.E., and Harry S. Mustard, M.D.

This group and the Editor will take the *American Journal of Public Health* as it now is and attempt to make it an even more effective instrument for the dissemination of authentic public health information, more thoroughly representative, if that is possible, of the interests now alive and those coming to birth in the public health profession. Before anything is done to effect what they all hope will be improvements, suggestions and comments from those whom the *Journal* is designed to serve will be most heartily welcomed.

WHAT WE OWE TO VETERINARY MEDICINE

THE December number of the *Journal of Comparative Pathology and Therapeutics*, founded by Sir John McFadyean, is dedicated in honor of its founder and editor, who is now 84, but still active physically and mentally. Five men of international reputation, contemporaries of Sir John, were asked to contribute short articles each from his own particular viewpoint in regard to the profession and Sir John's contributions. They include Bulloch of England, Leclainche of

France, von Ostertag, Schmaltz, and Mohler, Chief of our Bureau of Animal Industry. Americans, and especially the veterinary profession in America, owe much to Sir John.

There are few men who have covered so much ground and covered it so well as Sir John has. Not only has he devoted himself to pathology and therapeutics, as the title of the journal indicates, but he has written also on biochemistry, immunology, parasitology, and other subjects. He has studied anthrax, blackleg, cancer, glanders, hog cholera, epizootic abortion, pneumonia, tuberculosis, and other subjects, mainly from the animal standpoint. It is not too much to say that his studies and writings have guided much of the thought and work, especially among veterinarians, in the United States.

He has always paid particular attention to prophylactic measures. He was one of the earliest in the field of preventing contamination of milk by pathogenic organisms. Curiously enough, England is behind America and other parts of the world in the control of milk, in spite of the wonderful leadership she has had.

Sir John has done a great deal of work on animal tuberculosis and its relation to man. At the London Congress on Tuberculosis, following Koch's astounding claim of nontransmissibility from cattle to man, Sir John and the writer were selected to speak before the general meeting to combat the ideas advanced by Koch. Again, America leads in the eradication of bovine tuberculosis, due in this country almost entirely to the enlightened vision of Leonard Pearson, now carried on by our Bureau of Animal Industry under Mohler, but Pearson's plans were founded largely on the work and studies of Sir John. The studies of Sir John on glanders are generally credited as being responsible for the almost complete eradication of this disease from America.

The editor of this *Journal* has for years advocated a closer relationship between the veterinary and medical professions and has done as much as he could to bring more veterinarians into the American Public Health Association. At our recent meeting in New York we had a number of valuable papers from veterinarians. It is our hope that our relations will grow closer and closer because every year brings the proof of the close relationship between animal diseases and those of man.

We join with England in doing honor to Sir John and wishing for him many years of usefulness and happiness.

PUBLIC HEALTH EDUCATION*

Read It Before You Print It—What reads crystal clear to the writer may read quite differently to some other person. Of course the health officers were not responsible for the implication in this quotation from a New Jersey newspaper:

No explanation was given as to how the malady was introduced into the village, although it was said Federal and State health officers have visited the place.

To guard against double meanings, and other forms of confused writing, try to hold your copy on the desk for one day at least—a week is better. Then re-read it before putting it to use. Incidentally such a procedure would be likely to cut down the cost of “author’s corrections” of printed matter.

“Your Health” Broadcasts Continue—And it is not too late to consider their introduction into schools, or to take up the organization of listener groups of mothers, P.T.A. members, church or women’s club groups.

The program is broadcast every Wednesday from 2:00 to 2:30 P.M., eastern standard time, over Red network of NBC. For details about school or group use of the broadcasts write to Dr. W. W. Bauer, A.M.A., 535 N. Dearborn St., Chicago, Ill. Dr. Bauer will send a list of topics and of stations.

Health groups and others interested should prod the local stations so as to offset any possible commercial competition for the time.

How It Has Been Written—Probably some of our readers would like to consider varied forms for presenting a health message.

The first example is from New Mexico, a newspaper column written by Charles M. Cree, Director of Public Health Education in the State Bureau of Public Health:

It is funny	And when the
That some people	Doctor is finally
Who profess	Dragged in and
To love their	It is too late
Children	For him to
Will delay and	Help a great deal
Delay if one	The righteous
Of the family is	Parent will
Sick before	Claim the M.D.
They call in	Is a bum doctor.
The Doctor	Because he wants to
And sometimes	Shift the blame
It is so	From himself
Necessary for	At any cost
The Doctor to	So the poor
Come at once	Physician is often
I mean right now	Made the scapegoat
If he is to	For the parent's
Do any good	Foolishness

Expansion in Canada—At the 1937 meeting of Canadian Public Health Association one of the resolutions expressed

... its appreciation of the action of the Dominion Government in strengthening the Department of National Health by ... the restoration of the divisions of Publicity and Health Education, and Maternal and Child Welfare ...

“Musclebound with Caps” —“The Proofroom” is a valuable and definitely interesting department in *Inland Printer* (Chicago, Ill.), a leading journal of the printing industry. Recently a correspondent wrote about a bus card that

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

... began about like this: "Abraham Lincoln, When President of the United States, Before The Day Of The Auto"—every single word starting with a capital letter. Would you call that a strong style?

Said Editor Teall in reply:

Decidedly not! It is weak—spotty, like a case of measles. The capitals lose their character when used so indiscriminately. They are like cusswords overdone. There is nothing weaker than "strong language" dished up too liberally.

Capitals are used to mark off the start of a new sentence, and for proper names and titles of respect. In headlines or any sort of display matter, they should be used sparingly, on main words only. On words like "and," "of," "the," they are completely out of place.

There is no inherent strength in capital letters. They are like italics, used for contrast; the capitals with lower-case, and the italics with Roman. Text all in caps is not strong; it is actually weaker than the combination of upper- and lower-case. Try covering half the line, and see how hard it is to "get."

The fewer capitals we use, the stronger are the ones we do employ.

Interpreting Your Illustrative Cases—To publicize health agency cases is a simpler job than to explain via case stories much of the work of family and child care agencies. But it is easy to get into the much quoted "rut"—presenting illustrative cases in routine fashion. Moreover some of the less tangible phases of health service fail to get into case stories. This is difficult writing.

"The Case Worker Interprets" is a mimeographed pamphlet reporting what 9 agencies or groups of agencies did toward better case presentation. Every division or bureau, or individual staff member who supplies case material, in addition to those who do the writing, speaking, or broadcasting, should be interested. Copies could be circulated. A staff meeting could discuss the projects to consider possible adoption of one of them. Several of the projects offer possibilities for joint participation by the local or state group

of health agencies. Joint study and participation with a group of family and child care agencies may be considered.

Get "The Case Worker Interprets" from Social Work Publicity Council, 130 E. 22d St., New York, N. Y. 25 cents; special rates for quantity lots.

Holiday Greetings—In Texas a holiday greeting sheet accompanied the regular mailing of *Bulletin* of the State Department. Printed in green, red, and black, with the face of Dr. Cox inside the wreath, and three paragraphs of which here is one:

It is impossible for me to write a personal letter of thanks to the thousands of Texans who have assisted the cause of public health during the past year. Please accept this substitute. I wish that I might take you by the hand and say "Thank You."

Ohio Public Health Association used a slip for envelope enclosure. Large size Christmas Seal, and "Merry Christmas and Happy New Year," with the name of the Association.

Connecticut State Department mimeographed a sheet bearing a typographical Christmas tree. The text started with these words:

Health is the supreme gift for 1938 which the State of Connecticut plans for all its citizens from the babe in arms to its oldest residents.

Next year when more of you may be sending greetings it may be well to remember that to get an interested reading you should not use all capital letters if your message includes more than a half dozen or so words. Some may wish to point out that many health gifts await the readers in the course of the year, subject only to their interest and care, and that the department or the association will continue to remind them of what is theirs for the taking; for others less fortunate, service will be rendered that they too may claim health gifts. Some may

choose to place emphasis in one direction. Connecticut singled out diphtheria and pneumonia.

Fifty years ago hearts were saddened in many homes throughout the state because 2,863 infants were missing from their Christmas festivities. This year the family circles are lacking only 770 infants, and 2,093 more infants are sharing in the Christmas fun than would have, had the health conditions of fifty years ago prevailed.

Health Education First by Television—"The first successful transmission of a public health message by television was made on Oct. 7, when the New York State Department through the coöperation of the National Broadcasting Company" gave a demonstration before a group of health authorities.

A sound motion picture, "Public Health in New York State," prepared by the department's Division of Public Health Education, was projected in the television room of the RCA building, and by means of special apparatus was viewed several floors away by invited guests. Addresses were given over the television system by Edward S. Godfrey, Jr., and Homer Folks . . . At the same time, the entire program was sent from the television transmitting tower on top of the Empire State Building for the general public within the receiving radius of the station.

Just as it was the first official body to use radio in broadcasting health programs, the department is the first health agency to send a motion picture film by television. In 1931 an attempt was made to send three of the department's animated health cartoons from a station in New Jersey to a receiving station outside of New York City, but was unsuccessful.

"Making Bibliographies Alive"—Public health workers have much use for reading lists or bibliographies. Life is too short, and publication is too diverse and too rapid to get along without them. But too many of such "helps" are hindrances, or at least offer little aid to the busy student or practitioner.

Several uses of bibliographies are

suggested by I. M. Cooper in *Special Libraries*:

The purpose may be fourfold: To educate those who know little or nothing of the subject; to incite further specialized interest and research among students, young or advanced; to create and promote general popular interest in historical, economic, technical, commercial phases of said subject; to encourage the intelligent workers themselves toward a realization of the wide importance of and diversified interests connected with their special job.

The actual examination of listed books is essential so that the titles may be "adequately annotated."

What does adequately, here, mean? It means putting oneself in the place of the prospective user of the bibliography and comprehending what he wishes to know, not what the annotator sees fit to let him know because of lack of imagination, vital interest, or printing funds. This does not mean writing an essay or being verbose; it means clear, strenuous thinking with the definite, objective service in mind. In the case of the kind of bibliography we have set out to compile it also means a flair for exciting interest in a way that will lead some to new fields and others to an enlargement of their specialization; at the same time meeting the approval of those already fully informed. Also from the point of view of the reference librarian, the research worker or the student, the annotations must prove the value of the whole as a tool in facilitating rapid service to inquirers with varying needs. What hours of futile expenditure of physical and mental energy would librarians be saved and what wear on nerves of waiting clients if annotations, when used, were adequately serviceable in eliminating material non-pertinent to the immediate call.

Not mentioned by the author, but a fair warning to our readers, is a reminder that the above is no job for a stenographer or an untrained student.

The bibliographer who wishes his tool to be "alive" cannot be a dead one himself. It is moreover necessary that he be an interpretative medium translating the material which he has brought together into a vitally important source of interest, refreshment, satisfactory verification, or detailed research.

From "One Way of Making Bib-

liographies Alive" in *Special Libraries*, 345 Hudson St., New York, N. Y. Dec., 1937. 50 cents.

Health in Newspapers: Part 3— We reproduce about half of one weekly release in the series called "Here and There With the Health Reporter." This is supplied free to newspapers by Edward Fisher Brown, Health News Service, 22 E. 40th St., New York, N. Y.

FOR RELEASE—Oct. 11th

Health Officials Meet

GATHERED together in their common fight to lower the death rate and promote the public health, prominent Health Officers from all over the country met in New York City last week. There was held the impressive 66th Annual Meeting of the American Public Health Association. Impressive because the program was fairly bristling with the names of nationally important health officials and because of the recognized importance of their common cause.

Notable, also, was the importance attached to the use of the proper food and a better knowledge of nutrition in improving general health. Special sessions were held each day for discussions on this subject by various Committees on Foods. That plenty of fresh milk, fruits and vegetables should be included in the daily diet of every human being in order to build good bodily vigor, was stressed over and over. Addition-

In Cities of 10,000 or More—The annual directory of "Health Officers in Cities of 10,000 or More Population, 1937," appeared in *Public Health Reports*, U. S. Public Health Service, Washington, D. C. Dec. 10, 1937.

A few of the larger cities reported their chief administrative officers, among whom we note the following:

Melvin P. Iseminger, M.D., Director, Public Health Instruction, Washington, D. C.

Dorothy Yoe Kalben, Director, Bureau of Health Information, Baltimore, Md.

Mary P. Connolly, Director, Division of Health Education, and Editor, *City Health*, Detroit, Mich.

Charles F. Bolduan, M.D., Director, Public Health Education, New York, N. Y.

Would not this annual directory be much more useful if all cities reported their staff members?

Anyway, dear Health Officers, won't you get the health education people into the picture?

A Week and Six Months—"Empire Health Week" (Oct. 3-9, 1937) was planned to be a particularly spectacular affair in England,

... for it has been selected for the opening of the national health campaign which is to be carried on by successive stages until next March. ... The campaign is to be divided into 5 periods. October will be devoted to a general introduction to the campaign, the keywords of which will be "Towards a Fitter Britain—Use Your Health Services," which is an effective complement to the traditional Health Week Slogan, "Self Help in Health." November and December will be devoted to the maternity and child welfare services; January, 1938, to the school medical and dental services, and the milk-in-schools scheme; and February to the tuberculosis and other services for adolescents and adults. In March, 1938, there will be a link-up with the National Fitness Council, who will draw attention to the facilities already existing for physical training and recreation, and to the further facilities to be provided under the Physical Training and Recreation Act, 1937.

Throughout these months some millions of leaflets will be issued, and posters will be displayed by local authorities; a number of meetings will be organized by local authorities which will be addressed by members of all political parties, and other ancillary methods will be adopted such as the display of films of special health interest.

"Ask at the Post Office" will be one of the dominant slogans. Every post office will display a notice reading "Particulars can be ob-

tained at the counter about the health services in this district, including the addresses of the antenatal clinics and child welfare centres, and the times at which they are open." It is suggested that the "particulars" should take the form of a leaflet headed "Health Services," which could be handed to inquirers or shown to them, and which would contain details of local maternity and child welfare services referred to in the notice, information about such matters as the way to get an ambulance, the address of the local medical officer of health, the vaccination officer, etc., and the local hospitals, with their out-patient hours. A good selection of attractive outdoor and indoor posters, traffic cards for vehicles, book marks, mounted cards and folders, suitable to the special topic of each month of the campaign will be available for free distribution through the Central Council for Health Education.

From *Mother and Child*, 5, Tavistock Sq., London, W. C. 1, England. Oct., 1937. 9d.

Not Too Old to Learn—For workers in adult health education we quote some paragraphs from "Nisi Cresco," by William McAndrew. *Journal of Adult Education*, 60 E. 42d St., New York, N. Y. Oct., 1936. 75 cents.

Among those who have put life and hope into the service of adult education, I should like to sing a hymn of gratitude to Edward Thorndike.

Edward Thorndike is a prime antagonist of the old belief that we old chaps cannot learn anything. What he and his fellow workers have done is to overturn certain ancient proverbs of pessimism and despair. The Thorndikians have not denied the truth of the old adage that you cannot teach an old dog new tricks; they have doubted that an old man has to be considered a dog. By experiment and measurement they have shown that adults can learn anything they need to know. As I understand it, they have taken away from those who decline to exercise their minds the alibi of inability and have substituted the real reason, laziness. But laziness, as wise men from the time of Socrates have preached, is curable. The sovereign remedy for dislike of work is work.

From under Columbia University's dome, the same roof that shelters Thorndike, Walter

Pitkin issues his joyful gospel: "Life Begins at Forty." It does, says Walter, if you make it. It seems to me that the proper line for us teachers of adults to take is in this direction:

"How old are you, sir?"

"Sixty."

"Good! Life begins at sixty."

"What's your age, my good woman?"

"Seventy-three."

"Fine! Life begins at seventy-three."

Who can deny that life begins with every day on which one learns something worth knowing? Who can deny that every day one can, by intending his mind to it, as Sir Isaac Newton says, learn something worth knowing?

Jeremiah Jenks, reviewing the careers of Benjamin Franklin, John Quincy Adams, Abraham Lincoln, and many others, was moved to conclude that the best years of a man's life are the last ten years. And each of us, be it noted, is living in the last ten years of his life so far.

This idea gives a needful punch to the work of adult educationists who have to contend with the suggestion, prompted by indolence, that it is too late in the afternoon to begin anything.

The remainder of the article makes the application to the educators themselves! Some time we may quote those paragraphs.

Something Has Been Started—At least we hope so. Last October the A.P.H.A. had its first "hobby show" for members, with the prospect of repeats at future annual meetings.

Now the New York City Department of Health has put on its first hobby show as a phase of morale building. The first announcement listed 23 entrants, and invited all to—

See how your fellow-workers spend their spare time. See samples of their fascinating collections and products. Most of the entrants will be present—and will tell you all about their hobbies at the slightest hint.

Drama and News by Radio—During the spring of 1937, as a part of its health education program,

... the New Haven Health Department sponsored a series of radio presentations

through the facilities of Station WICC from its New Haven studios. These broadcasts, in the form of sketches, blending the historical with the present, dealt with a variety of public health topics. Many staff members of the department as well as specialists from outside the department, participated. Among the titles of the broadcasts were "Fifty Years Ago—An early meeting of the New Haven Board of Health," "Milestones of Health," "The Story of Vaccination," "The Conquest of Diphtheria," "Stars Along New Haven's Milky Way—the Story of Pure Milk," "The Foe of Youth—Tuberculosis," "A Perfect 32—Dental Hygiene," "Pneumonia Control," "Public Health Nursing." These programs were presented at an early evening period of 15 minutes each Friday night.

The current series of radio programs began in October 1937, at 4:30 to 4:45 Friday afternoons.

The title of this broadcast is "Health—Here, There, and Everywhere." An attempt has been made to present up-to-the-minute news and comment in the broad field of public health. The material has been compiled from public health reports, medical reprints, and the daily and weekly press, edited by Paul H. Stevens, the department's Public Information Assistant, and presented in chatty items by the Health Officer and members of the department's staff.

We quote 2 of the 7 examples of these items as reported in *Health* (Dec., 1937), issued by the department:

We wonder if any of you listeners have ever heard of lipid pneumonia? That's a funny name. Well, lipid in medical parlance means fat. From many sources cases of fat pneumonia have been reported, usually in infants and children under 2 years. And what do you suppose has been the cause of most of these cases? Nose drops—oily nose drops. The common use of the oil nose drops in young children has been found to be dangerous because in the usual struggle while the medication is being applied to the youngster's nose some of the substance is sucked into the lung. When once the microscopic feather cells lining these air passages are soaked with oil they cannot function. The function of these lining cells is to remove foreign particles and prevent material from gaining entrance to the lung. The oil, once in the lung, acts as an irritant and starts up an inflammatory process ending in a serious long-drawn-out type of pneumonia. So you see, oil drops should only be

used in children under the direction of a physician. Avoidance of self-medication is one of the first principles of good health.

Do you know that some people still wear a bag of camphor around their necks every winter? Why do you suppose they do it? Here's why. Because of a superstitious belief that it will prevent pneumonia and influenza. This practice of wearing a camphor bag around the neck, of course, does nothing of the kind. The only way so far, of preventing these maladies, is by staying away from people who have colds and by building up our bodily resistance. Milk, fruits, and vegetables, along with sufficient rest, will do much toward building that resistance.

Health Clubs for Negro Women
—As reported in *Health Bulletin*, Virginia Dept. of Health:

Health clubs for Negro women are organized by the department for educational purposes. Since October, 1932, clubs have been organized in 32 counties. The Negro Supervisors of Schools in these jurisdictions arrange meetings at central points for mothers, midwives, and others interested in health activities.

Mrs. Emily W. Bennett, R.N., of the department's Bureau of Child Health, gives a series of talks and demonstrations to the various groups. The members take The Healthy Baby course. Certificates are awarded by the Negro Organization Society to those completing it. In addition, club members make baby layettes, arrange for toxoid clinics, screen homes, and provide hot school lunches.

As it is impossible for the supervising field nurse to work in new counties and at the same time supervise the clubs organized two or three years ago, it is being advised that such organizations become a part of the school league. By this arrangement, it is hoped that the work will develop and become permanent.

Again Education Is Needed—
Dr. Ronald Hare, University of Toronto, writes of "Puerperal Sepsis and Its Prevention" in *Canadian Public Health Journal*, 105 Bond St., Toronto, Ont. Dec., 1937. 35 cents. In conclusion Dr. Hare says, as to one phase of the problem, that

... much may be done by an educational

program comprising the following points:

1. Better education for students and nurses in the technic of delivery in homes and difficult surroundings, as well as in the knowledge of etiology of infections which is now available.

2. Education of physicians already in practice by lectures, demonstrations, and refresher courses.

3. Education of hospital matrons and nursing superintendents in the part they should play in the elimination of infections from hospitals by control of carriers and infections among the nursing personnel.

4. Education of the public to take advantage of the facilities for antenatal examination now available and in the preventable dangers attendant on midwifery in the home.

5. Education of legislatures in the necessity for the provision of funds for the delivery of necessitous mothers, for skilled obstetrical assistance in case of need, and for the isolation and care of infected cases.

Eleven Slogans—Here are rallying cries for the successive early diagnosis campaigns:

1928—You May Have Tuberculosis—Let Your Doctor Decide; 1929—Early Discovery—Early Recovery; 1930—Protect Them from Tuberculosis; 1931—Tuberculosis—The Foe of Youth; 1932—Tuberculosis Causes Tuberculosis—Every Case Comes from Another; 1933—From Whom Did He Get It? To Whom Did He Give It?; 1934—Tuberculosis Robs You—Public Health Protects You; 1935—Fight Tuberculosis with Modern Weapons; 1936—Fight Tuberculosis with Modern Weapons; 1937—Uncover Tuberculosis by Modern Methods; 1938—Tuberculosis Undiscovered Endangers You.

Learning Versus Teaching—Reviewing "Advances in Public Health Nursing," Elizabeth G. Fox, said:

As for health education, so-called, we are beginning to have some insight into how to make the message of scientific medicine mean something vital to the individual. We have been called health messengers; and in that guise have naively thought that we could carry nuggets of science from the laboratory and deposit them on the doorsteps of the people, and that good results would follow. We were blind to the truth of John Dewey's statement that no more is something taught when nothing is learned than is something sold when nothing is bought. We thought

that the factors of interest and of voluntary activity, without which teaching is worthless, could be aroused through reason. We tried to make up by vehemence and persistence for what we lacked in insight, and when we failed we wrote our patient down as uncoöperative. More recently we have realized that getting people to adopt new ways is a science based on an understanding of the psychic drives which govern behavior. Even so simple a thing as getting a prejudiced mother to believe that pasteurized milk is safest for her baby may call for something much more subtle than a rehearsal of scientific evidence.

This is not to say that nurses have not been successful in the past in overcoming resistance. The wonder is rather that we have been so often successful. But candor compels us to admit that we have also been baffled time and again and have laid our failure to the contrariness of human nature. Now we are beginning to see that had we understood human nature better we might have discovered the cause of the seeming contrariness and have made our assistance acceptable to the patient.

In short, public health nursing has advanced to the stage of knowing that it is not enough to be a messenger conveying a standard package which we have selected in advance as good for any recipient. We must have our goods in a variety of forms and wrappings, and our methods of delivery must be as various as are the people with whom we are trying to establish fruitful relations. The prospective recipient's own plans and desires and interests must be our guide.

In *A.J.P.H.* and *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Dec., 1937. 35 cents.

Leadership in the Berkshires—As reported in *Bulletin*, Massachusetts Society for Social Hygiene, Little Bldg., Boston, Mass. (Dec., 1937):

Under the chairmanship of Dr. Modestino Criscitiello, and with the active coöperation of the *Berkshire Evening Eagle*, the Berkshire District Medical Society, the local Health Department and the Pittsfield Council of Social Agencies, the committee has sponsored a series of 6 newspaper articles, which were given prominent space in the *Eagle*. These excellent articles were prepared by Dr. Willys Monroe, Pittsfield's Health Officer, Viola Vreeland, R.N., of the House of Mercy Hospital, and a Pittsfield physician, whose sense of

professional ethics constrained him to remain anonymous.

This project illustrates what a voluntary agency can do most effectively in a community. Pittsfield has made use of the machinery at its disposal to educate the general public on the subject of syphilis—its medical, public health, and social aspects.

Hygeia, January, 1938—Some of the articles in *Hygeia*, 535 N. Dearborn St., Chicago, Ill.:

New Year's resolutions . . . Preventing heart attacks (radio address) . . . Sex education for young children ("folly of fables and wisdom of truth") . . . Why condition the air? . . . These teeth of mine (teeth of savages) . . . The making and unmaking of a quack . . . "Occupational diseases" in children . . . Government's interest in violent and sudden death . . . Overcoming worry (habit control) . . . Occupational diseases of musicians . . . Some obesity "cures" and "treatments" . . . Two common intestinal worms . . . Diseases of the eye . . . New books on health . . . Questions and answers.

Under "School and Health":

The classroom teacher at work . . . Health teaching in January . . . Hygiene and the use of the dictionary . . . Everyday health lessons in a rural school (San Luis Obispo, Calif.) . . . How shall we teach safety to children? . . . New health books for teachers and pupils.

Tell the Public What You Do—
Ohio Health News, Columbus, Ohio, quotes the newspaper clipping below from Dr. J. A. Carter, Health Commissioner, Batavia, Ohio. The *News* suggests that such information is well worth printing in local newspapers. (It should be offered to the editors in the form of an interview with the health officer.)

The Clermont County District Health Department exists for the sole purpose of rendering service to the people of the county in matters pertaining to their health and welfare. All of its services are free of charge to rich and poor alike. In so far as it is physically possible for the staff to do so, every request for service is given prompt consideration. No requests for bedside nursing or for private medical care can be complied with. Certain of these services are

rendered in coöperation with the family physician.

For general information there are listed below some of the services to which residents of Clermont County are entitled and which will be rendered on request. Home visits by the nurses to any case of tuberculosis. Home visits by the nurses to any expectant mother, when requested by the family doctor. Home visits by the nurses to any crippled child. Home visits by the nurses whenever the health of any infant makes this desirable to the family doctor. Certificates showing official registration of birth for every child whose birth is reported. Assistance rendered anyone in Clermont County who desires a birth certificate. Diphtheria antitoxin supplied free to any physician in the county. Smallpox vaccine virus supplied to any physician in the county. Laboratory examinations where requested by the family physician. Investigation of every reported case of communicable disease. Investigation of well water for any resident. Investigation of every complaint of nuisance. Coöperation with milk producers to provide clean milk. Consultation regarding any matter of sanitation. Coöperation with P.T.A.'s and schools to provide physical examination of children before entering school. Follow-up to aid in obtaining correction of defects found in pre-school round-up. Immunization of school children against diphtheria and smallpox, where consent is given by parents. Examination of sight and hearing of school children. Physical inspection of all school children that time will permit. Inspection of school children at time of threatened epidemic.

DATES AHEAD

The "Little Red" one room cottage sanatorium was opened in February, 1885.

The first hospital in the modern sense of the word was opened in February, 1752.

Daniel Boone was born Feb. 11, 1735.

St. Valentine's Day comes Feb. 14.

And George Washington's birth makes February ever to be remembered.

The first visiting nurse went on duty in March, 1877.

St. Patrick's Day, March 17, has some health significance.

Spring begins March 21.

National Negro Health Week is announced for March 27–April 2.

April Fool's day, April 1, may be a time for telling how people fool themselves—with many health superstitions.

And then the Early Diagnosis Campaign is on throughout the country.

Details about the unfamiliar dates noted above would be found in "News Almanac" and "Almanac Notebook" issued by Community Chests and Councils, Inc., 155 E. 44th St., New York, N. Y. 50 cents.

COMMERCIAL GADGETS

"Debunker" is a handy device for still and motion photography. Two revolving circles in a 2½" by 5" card give quickly exposure time, etc., for motion, indoor, and outdoor pictures. Price 50 cents, but Don Graf, 330 W. 42d St., New York, N. Y., will send it, you to pay, or return.

With the increasing use of planograph and offset, consideration may well be given to special devices for making the most of the processes at the least expense. One of these is "Fototype," card board letters of standard type faces, for the easy production of headlines, captions, and text set in not smaller than 12 point type. A composing stick costs \$2.50, the letters about 5 for one cent. Any office worker can set the type, which is then pasted on the sheet with other copy. Address: Fototype Co., 629 Washington Blvd., Chicago, Ill.

If you have letter size, or smaller, sheets you wish duplicated in photostat style, the "Foto-Copyer" is offered by Duplico Corp., 28 East 22d St., New York, N. Y. Birth certificates, statistics, copies of any manuscript or printed material desired for reference, or to pass on for examination may be produced by a clerical worker at a cost of 7 cents a page for the paper. A substantial copy of a draft of the annual report could be made for gen-

eral scrutiny. Dr. Bauer in Health Education for Adults has in mind the desirability of such copies when submitting important manuscript to editors or publishers.

MAGAZINE ARTICLES

Articles are listed here for personal reading, office memoranda, bulletin boards, house organs, the writing of letters to the editors, etc.

"Angel in Furs," by W. B. Courtney. *Colliers*. Nov. 26, 1937. "They call Mildred Keaton a traveling nurse. She travels by dog sled, by airplane, and by kayak." "Keaton," say the people of Nome, "is the most beloved woman in Alaska."

"Get Its Number," by L. I. Dublin. *Colliers*. Dec. 11, 1937. "Not long ago doctors had to stand by almost helplessly when pneumonia struck. Now it's different. Science is now fighting *B. Pneumococcus* with the test tube."

"The Government Crusades for Good Health," by Dr. Thomas H. Parran. *Democratic Digest*, Women's Division of Democratic National Committee, National Press Bldg., Washington, D. C. Dec., 1937. 10 cents.

"Health to All of Us." Editorial. *Colliers*. Nov. 27, 1937. Health education, better living conditions, and better health for all.

"Knockout Drops—New Style," by H. Lees. *Colliers*. Nov. 20, 1937. "Ether took the physical pain out of operations: a new batch of anesthetics spare the patient mental distress as well."

"Organized Medicine 'Sees Red,'" by James Rorty. Doctors object to group medical service in Washington, D. C. *Nation*, 20 Vesey St., New York, N. Y. Nov. 6, 1937. 15 cents.

"Political Surgery." Editorial. *Nation*. Dec. 11, 1937. 15 cents. What happened to the \$100,000 medical-economic survey in California.

"Why Do They Die?" by E. Keating. *Literary Digest*, 233 4th Ave., New York, N. Y. Jan. 15, 1938. 10 cents. Why babies and mothers die, and what is being done about it.

MOTION PICTURES

"Descriptive List of Eastman Classroom Films." There are now 39 pictures described briefly under "Health" in this catalogue. Eastman Kodak Co., Teaching Films Division, Rochester, N. Y. *Free*.

"Indoor Movie Making" is a mimeographed pamphlet. Bell and Howell, 1801 Larchmont Ave., Chicago, Ill. *Free*. Part is general, part is given in terms of Filmo cameras.

A summary of important fundamentals of indoor movie making with artificial lighting. Important differences in lighting practice for black and white, and color photography are considered and tabulated in chart form.

In Sept., 1937, an injunction was granted in Detroit which prohibited the police from interfering with a performance of "Damaged Lives."

"For All Our Sakes" is a detailed scenario of the talking slide film of that name, together with information for its projection by one of the talking slide projectors which is quite different from the stereopticon. Am. Social Hygiene Assn., 50 W. 50th St., New York, N. Y. 24 pages. 10 cents.

"Let's Open Our Eyes." One reel film dealing with syphilis. 1,000 feet. 15 minutes. 35mm., also 16mm. National Motion Pictures Co., Mooresville, Ind.

The film points out that closing our eyes to the seriousness of the problem does not prevent the danger from existing none the less. It advises those who know they have become infected to go to a competent doctor or clinic at once. Faithfulness to the treatment schedule is stressed. The film also advocates routine Wassermann's for pregnant women and in all physical examinations. It closes with the message that syphilis can be controlled by energy, organization, and intelligent coöperation.

"Life Saving" is a new 2 reel sound picture (35mm and 16mm) issued by the Dept. of Agriculture, Washington, D. C. If not familiar with the distribution methods of the department it would be well to write for information.

"Your Health Department and What It Means to You." 2 reels. 35 mm. and 16mm. 2,000 feet. 30 minutes. National Motion Pictures Co., Mooresville, Ind.

It is the purpose of this film to show the public the activities, accomplishments, and goals of health department programs, thereby creating the essential coöperation and support of the public. Incidentally, it teaches many valuable health lessons, thus accomplishing a dual purpose.

NEW

New to us is *Bulletin*, Belmont Health Department. What state, you ask? There are 20 to choose from, but in the A.P.H.A. membership list we traced the name of the health officer named on the first page. *This Belmont* is in Massachusetts.

Canada's Health News, Health League of Canada, 105 Bond St., Toronto, Ont. A news bulletin supplementing the magazine, *Health*, the two issued alternately.

RADIO

"Keeping Well." The second series of radio talks broadcast by Baltimore Health Dept. and Medical and Surgical Faculty of Maryland; 145 talks or dialogues; 280 page paper bound book, with contents and index. 50 cents.

"Radio Broadcasting Stations of the United States." List of all stations; map (with time divisions) showing 138 NBC network stations. National Broadcasting Co., Rockefeller Plaza, New York, N. Y. *Free*.

"The Dentist Says" is a non-commercial program of dental health education via broadcasts from several

stations, together with a teaching plan book, and weekly copies of the broadcasts. The story form is used. Tuesdays as travelogues, Fridays as personal experience stories. The latest information is that the series is being broadcast over WMCA, New York; WIP, Philadelphia; WFBM, Indianapolis; WBAA, West Lafayette, Ind. For samples and full particulars address Dr. George W. Clapp, 220 W. 42d St., New York, N. Y.

A broadcast on venereal diseases was given over Station WRVA, Richmond, Va., as a feature of 1937 National Negro Health Week. The speaker was Dr. D. Webster Davis, Jr., of the Richmond Medical Society. In *National Negro Health News*, U. S. Public Health Service, Washington, D. C. July-Sept., 1937. Reports of the Health Week mention 327 radio talks in various cities.

"Getting Ready for School" is a dialogue on school health education. A paragraph from the announcer's statement:

We take you into the Home Bureau office where Mrs. Brown, President of the Home and School Club at Cramer's Corners, and also member of the Home Bureau, is waiting for Mrs. Graham, the Home Demonstration Agent. Mrs. Brown has 3 children, 2 in school and 1 just starting this year. Miss Grout, Consultant in School Health Education (Cattaraugus County) comes into the office, also to see Mrs. Graham, and sits down next to Mrs. Brown. Presently they begin to talk." (The conversation which follows interweaves facts about school child health conditions, and the program of Cattaraugus County school health service.)

The Health League of Canada (105 Bond St., Toronto, Ont.) has had the coöperation of 35 broadcasting stations in giving a weekly 15 minute health talk. The December and January topics included:

Cod liver oil . . . When to call the doctor . . . Diphtheria . . . Health insurance . . . Tuberculosis . . . The school child . . .

Typhoid fever . . . Results of milk pasteurization.

In a series on "Programs That Have Made Station History" we learn about Dr. Carlton's health talks. *Radio Daily*, 1501 Broadway, New York, N. Y. (June 7, 1937; 5 cents), says:

On May 31, WSJS, Winston-Salem, N. C., celebrated the seventh anniversary of its oldest continuous program. Every Monday evening at 8 o'clock since June 1, 1930, Dr. R. L. Carlton, head of Winston-Salem's City Health Department, has brought to the community a personal message on the subject of individual and public health or has presented some outstanding figure in the field. The program on May 31 was his 364th.

One of the principal reasons for the ever-increasing success and influence of the health program is the fact that Norris O'Neil, general manager of WSJS, has never exercised censorship on the doctor's remarks, believing that the station's audience has a right to hear frank discussions of any and all health problems, and that radio is the best means of bringing these discussions to it.

All opportunities to sponsor the program are turned down. Dr. Carlton's Health Talks are strictly a public service.

A personal experience in dealing with the "censor" of a national broadcasting chain is related in "What Can You Stomach?" in *The New Yorker*, 25 W. 43d St., New York, N. Y. Oct. 9, 1937. 15 cents. Written by an Associate Professor of Clinical Orthopedic Surgery at Columbia, Dr. Armitage Whitman. In view of the recent Mae West incident it would seem that doctors are more suspect than actresses with a reputation. Sample:

"No, Doctor, you can't say 'body' of the patient. 'Body' sounds like a 'dead body.'"

So far this department of the *Journal* has heard of no audience-protests against the use of syphilis or venereal diseases in any of many broadcasts over the country. On the other hand, one of the early December commercial programs brought out "a flood of protests." The skit was characterized as "obscene," "indecent," "vulgar,"

"filthy," "sexy," and so on. Apparently the "good taste" barrier so often urged by the chains as barring mention of syphilis did not hang very high for a commercial.

"A Well Person is a Community Asset. A Sick Person is a Community Liability." This heads a placard poster announcing weekly broadcasts over 5 local stations. Community Chest, Los Angeles, Calif. Also another: "Guard Your Health," "See Your Doctor While You're Well" with announcement of a weekly broadcast, "Heartbeats of the City."

"What's Wrong with This Radio Talk?" headed a short broadcast, announcer and director of a public health nursing service being the participants. On another page were given 8 corrections, including a sample story presenting the essential information in the uncorrected statement. Worth looking up. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Aug., 1937. 35 cents.

EXHIBITS

As reported in *Journal of Home Economics*:

Much interest was shown at the Eastern States Exposition in the Connecticut 4-H exhibit on home care of the sick in which simple homemade comforts were featured. The wheel chair improvised from a rocker on roller skates frequently brought the ejaculation, "Now, who ever thought of that?"

"J. R. C. Booth at the South-eastern Fair," by B. Worthen, in *Junior Red Cross Journal*, Washington, D. C. (Jan., 1938), tells how a group of Red Cross Juniors con-

structed and managed a display at a fair. Since health is so large a share of the Junior program, this article prompts us to suggest that the juniors might put on health displays at other fairs, if the idea was brought to their attention.

"The Paris International Exposition," by L. Taylor. *Trained Nurse and Hospital Review*, 468 4th Ave., New York, N. Y. Nov., 1937. 20 cents. Brief description of the "Palace of Discovery," part of which

... might have been built for the special interest of the nurse, so thorough and interesting is the section which deals with the history of medicine.

The whole job of "Organizing Educational Exhibits" for convention displays is described under that title in *Journal of Health and Physical Education*, Ann Arbor, Mich., Oct., 1937.

An actually satisfying holder for card signs and placards, to hold them upright on desk or table, in window or elsewhere, is "klikeasel," a simple device at \$1.25 for 12, using 2 to a card or sign. Obtain from local window display house, or Window Advertising, 175 5th Ave., New York, N. Y.

For window display and other exhibit planners corrugated paper in a wide range of color, texture, and design is available through Dennison Mfg. Co., Framingham, Mass., and Window Advertising, 175 5th Ave., New York, N. Y. Each offers a line with distinctive qualities, each has additional materials for display purposes, and also makes letters cut from corrugated paper.

BOOKS AND REPORTS

Public Medical Services. A survey of tax-supported medical care in the United States—By *Michael M. Davis*. Chicago: University of Chicago Press, 1937. 170 pp. Price, \$1.50;

In introducing this small but compactly written volume, Mr. Davis first of all paints a useful historical background in which he emphasizes the initiation of public medical services as a part of relief activities for the indigent, and later brings out the way in which the picture has been modified by a quite different motivation—a desire to meet broad community needs primarily in the public interest rather than the emergency needs of an individual. The hospitalization of mental diseases and of tuberculosis and the provision of clinics for the treatment of syphilis are obvious examples of the later tendency.

Mr. Davis reviews existing provisions for home and hospital care of various types at direct government expense and also the indirect support of voluntary institutions through financial grants. In an interesting table reviewing statistics for the year 1929, he estimates that of the total medical bill of \$3,600,000,000, \$2,830,000,000 were paid in fees, \$500,000,000 by taxation, \$170,000,000 by insurance, and \$100,000,000 by charity. Thus two-thirds of the cost of medical care was still borne by individuals on a fee basis, and of the remainder the major part by taxes. The book closes with an interesting consideration of quality of service and of the importance of community coördination. The author wisely emphasizes the importance of systematic pro-

fessional supervision of professional work which, while not always present in public medical services, is obviously much more effective there than in individualistic private practice.

C.-E. A. WINSLOW

Phenomenon of Local Tissue Reactivity and Its Immunological, Pathological and Clinical Significance—By *Gregory Schwartzman, M.D.* New York: Hoeber, 1937. 461 pp., 67 ill. Price, \$7.50.

The phenomenon of local skin reactivity, more commonly known as the "Schwartzman Phenomenon," was first observed by the author of this volume in September, 1927 (*Proc. Exper. Biol. & Med.* 26:207, 1928), in the course of his attempts to gain a more accurate understanding of factors and mechanism responsible for the systemic intoxications of infectious diseases. In order to overcome a hypothetical refractory condition of the animal cells, culture filtrates were given to rabbits by different routes on consecutive days.

When typhoid bacillus culture filtrate was injected intracutaneously and 24 hours later another dose was given intravenously a hitherto undiscovered local reaction occurred. Approximately 2 hours after the intravenous injection a blue discoloration appeared at the site of the skin injections made the day before. The discoloration rapidly increased so that within 4 hours the areas were dark blue in the center with a deep red zone at the periphery. The reaction reached its maximum size in about 5 hours when it was hemorrhagic and necrotic; sloughs formed about 48 hours after the intravenous injection;

these were followed by scab formation with healing in about 8 days. The appearance of a reaction 4 hours after the intravenous injection is illustrated by a colored photograph reproduced as the frontispiece.

Jules Bordet has written a foreword for the volume. In it he says:

The remarkable phenomenon which Dr. Schwartzman has studied with such ingenuity and perseverance has aroused the most vivid interest among bacteriologists and immunologists. From the very beginning his discovery has been justly recognized as an important scientific development. The discovery of the phenomenon was totally unexpected, it must be acknowledged, for if there is any field which has been minutely investigated from every point of view and conscientiously searched it is that of the reactions of the organism to bacterial products. One could not have suspected that in this field secrets still remained unraveled and surprises were in store for us.

The Schwartzman phenomenon, Professor Bordet suggests, is closely related to the phenomenon of Sanarelli. He states that:

Dr. Sanarelli had shown that an intravenous injection of *B. coli* culture filtrate, although easily tolerated by the control animals, elicits a fatal hemorrhagic congestion in the intestinal tract of rabbits which had previously received a sub-lethal dose of cholera vibrio. . . . It is highly probable that these phenomena determine the pathogenesis of certain complications in the course of infections.

This volume consists of 13 chapters. The first deals with basic matters such as terminology, general considerations, and quantitative estimations of potency of active principles. The second discusses bacterial filtrates and other products capable of eliciting the phenomenon; the third concerns physico-chemical properties. Subsequent chapters consider, interestingly and thoroughly, immunological behavior of active principles; immunity to the phenomenon; rôle of inflammation; methods of elicitation; reactivity of

malignant neoplasms; reacting potency of non-bacterial substances, nature of the active principles; immunological relationships of the phenomenon (in this it is shown that the phenomenon is not related to allergy); immunological, pathological, and clinical significance; and application to treatment of certain human conditions.

The material constituting each of the chapters is well systematized and each ends with a recapitulation. This method of presentation greatly facilitates reference and study.

The final chapter upon the application of the phenomenon to treatment of certain human conditions reveals how little of practical value to the clinician has resulted from recorded investigations in 10 years. Like the bacteriophage, the Schwartzman phenomenon holds intense interest for the research worker and its study is full of promise. The phenomenon offers an explanation for certain phases in the development of disease processes for which there has been up to now no lucid understanding. The author's conclusions as to the nature of the phenomenon are

. . . that the state of reactivity described deals with a hitherto unrecognized functional disturbance in the susceptibility of the animal tissue elicited by means of certain bacterial active principles and that the phenomenon of local tissue reactivity displays a mechanism whereby injury may be produced through the synergistic effect of bacteria and their products and also through the concerted effect of bacteria and their products and nonrelated anaphylactic processes.

Immunologists, and clinicians, too, will be glad to have assembled in one place the hitherto scattered mass of information already accumulated upon the Schwartzman phenomenon. For a great preponderance of the ingenious, painstaking, and illuminating work recorded herein the author is himself responsible.

The volume contains an ample bibliography (from which the titles of cited papers are omitted), an author index, and a subject index. It is an attractive addition to our libraries; the very name of its publisher is well known to be synonymous with superlative in the book making art. It constitutes another fine memorial to his high ideals.

A. P. HITCHENS

Pathology (Clio Medica)—By E. B. Krumbhaar, M.D. New York: Hoeber, 1937. 206 pp. Price, \$2.00.

The author has compiled a wide range of diverse developments in medicine, either indirectly or directly related to pathology, and has woven these into an intelligent, intriguing and educational volume. He has made careful and wise selections. The material is presented in a clear, straightforward, understandable form, showing a personal knowledge and interest in the material by the author. It is an excellent, concise presentation from which students in medicine or those interested in medical development can readily obtain authentic information concerning the mistress of medicine—pathology. The Chronological List of Pathologic Milestones and the Index of Personal Names, with the usual subject index, constitute valuable features and reminders.

Interest is attracted to the volume through its general compilation, size, and printing.

M. PINSON NEAL

The Baby's First Two Years—By Richard M. Smith, M.D. (4th ed.) Boston: Houghton, Mifflin, 1937. 122 pp. Price, \$1.75.

Dr. Smith's book on the care of the baby has been a standard manual for over two decades. This 4th edition has been revised carefully and new material incorporated to bring it up to date. It is written simply, clearly, and to the point. There are no superfluous or ob-

scure statements. The illustrations assembled in the middle of the book are very attractive and helpful. The chapter on "A Typical Day" is practical and should be of great aid to the perplexed mother. The handy guide can be recommended to mothers and prospective mothers without reservation.

RICHARD A. BOLT

Man, Bread and Destiny—By C. Furnas and S. M. Furnas. New York: Reynal & Hitchcock, 1937. 364 pp. Price, \$3.00.

Of the many recent books on nutrition for the general reader, this is one of the best. The authors, one a professor of chemical engineering at Yale, and the other, his wife, a former instructor in nutrition at the University of Minnesota, not only have presented the fascinating story of man's food in a comprehensive and reliable manner, but have produced a most entertaining narrative, sparkling with infectious wit and humor.

Appropriately using "Bread" in their title as synonymous with food generally, the authors begin their story with an interesting, if somewhat conjectural description of the diet of early man, then recount some of the early ramblings in the science of nutrition, and next proceed to a popular account of the physiology of eating and the proper functions in the diet of fats, carbohydrates, proteins, minerals, and vitamins. More is already known about vitaminology than they have told, but this is no disparagement of any modern book on foods, for discoveries in this field seem to come faster than printers can set type.

Other topics treated in this engrossing book include the effects of diet on the teeth, on mentality, and on stamina, and the food fads and follies, aptly characterized as "Gullible's Travels." There is also material on cooking and the psychology of eating, on the economic

aspects of the world's food supply, and on the future of food. An appendix gives data on the best sources of minerals and vitamins for the adequate diet.

That the authors have gone, in general, to the proper sources for their information is shown by a bibliography comprising 24 pages. There is likewise a good index. Anyone interested in the vital subject of food and its effects upon human health, as everyone should be, will find this book very much worth while.

JAMES A. TOBEY

The Measurement of Outcomes of Physical Education for College Women—By *Elizabeth Graybeal*. Minneapolis: University of Minnesota Press, 1937. 80 pp. Price, \$1.00.

This monograph is a report of an experiment carried out at the University of Minnesota in an effort to determine whether the college requirement in physical education for women could be proved justifiable. The subjects for the experiment were freshmen women entering the university in the fall of 1932. After the elimination of those who deviated from the normal to the extent that remedial work was indicated, they were divided at random into an experimental and control group. The experimental group participated in required physical education, while the control group were excluded from participation in required work, and a check was kept on the outside activities of both groups.

Subjects were tested at the beginning of the experiment in 4 objective tests—attitudes, knowledge, motor ability, and posture. They were given the same tests at the end of both 1 and 2 year periods. The attitude test used was developed by John Jacobsen, then on the Committee on Education Research at the university, and consisted of 161 items expressing varying attitudes toward health and physical education

which the students checked if they were in complete agreement with the statement. The knowledge test was constructed by a committee from the staff of the Physical Education Department for Women. It consisted of 355 multiple choice questions on physical education activities and health. The motor ability test was the Graybeal-Minnesota Motor Ability Test Batteries for College Women worked out for the purpose of this study along the line of Cozens' Tests for College Men and made up of strength and coordination tests. Posture was measured by grading photographically: (1) depth of spinal curve, (2) segmental angulation and body tilt, (3) position of head and neck. In addition to the above tests, at the end of the 1 and 2 year periods part of the Schneider Cardiovascular Tests were given.

Improvement in the functions tested was consistently noted for the experimental group, which was not true for the control group, at the end of both the 1 and 2 year periods. It seems unfortunate from the standpoint of the experiment that some of the colleges at the university do not have the 2nd year requirement in physical education, which meant that the group tested at the end of the 2 year period was comparatively small. The interpretation of those results therefore would seem less reliable. Dr. Graybeal concludes, "that the improvement in the functions tested, while not great in every instance, was demonstrated so consistently by the group who participated in the prescribed course, that the requirement in physical education would seem to be justifiable."

The tests selected by Dr. Graybeal do not measure, of course, all the outcomes of the physical education program, and we might question whether they are the best measure of the functions tested, but there can be no doubt that the experiment was scientifically

carried out, and the book is a well written report of that investigation.

RUBY J. CLINE

Proceedings of the 1936 Annual Conference of the National Society for the Prevention of Blindness. *New York: N.S.P.B.*, 50 West 50th Street, 1937. 134 pp. Price, \$1.00.

This volume of Proceedings contains the papers presented at the Annual Conference dealing with the following subjects: Saving eyesight in industry, eye health in relation to social work, rehabilitation vs. relief, eye health of college students and of school children, the nurses' approach to eye health, and sight saving classes. Data submitted for one state indicate that eye injuries represent 17.1 per cent of all injuries by industry, with machinery manufacture heading the list.

Considering the conservation of eye health, attention is directed to the preliminary examinations, inventories, and case records; periodic eye examinations; correction of defective vision; prompt first aid; sanitary working conditions; proper lighting; and venereal diseases. Tests to determine eye skill are described while the importance of a yearly examination of the eyes of college students as a part of the routine of every health service is stressed. It is made apparent that factors related to sight may have educational, social, and psychological effects upon the development of the child. Impressive financial data are submitted to indicate the value of preventive activities. Health administrators, educators, and social workers will find this volume of practical interest. IRA V. HISCOCK

Child Psychology—By Fowler D. Brooks. *New York: Houghton Mifflin*, 1937. 599 pp. Price, \$3.00.

This new book on child psychology by Professor Brooks deserves more than passing notice. It reveals the

same thorough scholarship and exhaustive research as his companion volume, *Psychology of Adolescence*. He has brought together the results of the leading investigators in his field, and has presented the material in a logical, impartial, clear, and systematic manner. The book covers the psychological development of the child from the prenatal period to adolescence.

Dr. Brooks is not wedded to any particular hypothesis or theory. He does not burden the reader with any special "school of thought." His book is really a compendium of thoroughly sifted scientific data bearing upon the normal growth and development of the child as an integrated individual. It cannot be too highly recommended as a reference volume.

It is completely documented with references to original sources and additional references to the material in each chapter are given at the end. The format of the book is excellent.

RICHARD A. BOLT

First Aid Textbook—American Red Cross (rev. ed.). *Philadelphia: Blakiston*, 1937. 256 pp. Price, \$1.00, cloth, \$.60, paper.

It has been 4 years since the last edition of this book appeared. Many of the same author-physicians participated in this revision. Not content with such formidable authenticity, the manuscript was then submitted to various national organizations and to additional individual specialists on mines, safety, electricity, snakes, fractures, drowning, poisons, rabies, etc. So without stretching the point, we may assume that after this careful preparation and scrutiny, anything which got past these experts and now appears in the text is at least relatively authoritative.

There are 14 chapters: on the need for first aid; anatomy and physiology of the body; dressings and bandages;

wounds; shock; wounds requiring additional consideration; artificial respiration; injuries to bones, joints and muscles; injuries due to heat and cold; poison; unconsciousness; common emergencies; transportation; First Aid kits.

There are 18 drawings and 153 photographs to illustrate the text. The type is sufficiently large throughout to be read even though the reader's hands are shaking. Pages are broken down into numerous paragraphs, numbered or headed with heavy type, as necessary. The authors do not indulge in long dissertations. The reader is never left in doubt. Sentences are often in the form of a command—"Do not rub." "Close the eye."

The preface by Harold F. Enlows, Director, First Aid and Lifesaving Service, American National Red Cross, closes with this statement: "Never has the need for first aid been greater than at present, when accident fatalities of the United States have reached such a proportion that, if those of a year were to happen on a single day, it would plunge the entire nation into mourning as the greatest catastrophe in recorded history."

But that was the preface in the 1933 edition. In the 1937 edition, not a word is said about the incidence of accidents. And for at least one good reason which comes to mind—the accident rate has reached such mighty proportions in this country that Mr. Enlow simply could not find words sufficiently adequate to express the increase over 1933.

To any who think a First Aid Textbook has to be stodgy reading, a glance at the opening sentence of Chapter I: "A heavy truck swings around a blind corner, crashes into an automobile and hurls it over an embankment. A man is pinned under the wreckage." And that is not all. Through "unskilled and ignorant handling, the man's spinal

cord is punctured by a broken bone, so that . . ." But no reviewer gives the plot away. Read it yourself. It is a thrilling book.

In this mad day of commercial lure through offering prizes of every conceivable sort, someone ought to start a movement to give this First Aid Textbook as a prize whatever be the pretext to every person who ventures out of his house. And since the inside of the house is not free from accidents, everybody should have a copy.

W. W. PETER

Handbook of Hygiene—By Joseph W. Bigger, M.D. (5th ed.) Baltimore: Wood, 1937. 405 pp. Price, \$4.00.

Only a few days ago we reviewed a book on hygiene and quoted the author as saying that something of an apology was necessary these days for writing still another book on this subject. The ink was scarcely dry when the present book came to hand. If we had not known something about the author we would have been inclined to pass this by, but reading it has brought its reward.

It is refreshing to find an author who has nerve enough not to follow the usual routine. He begins with a chapter on Vital Statistics, knowledge of which he justly says is commonly lacking among medical men and women. The communicable diseases are dealt with in groups according to their chief methods of spread and not according to the methods of prevention, as in the book mentioned above. The usual subjects treated in a book on hygiene then follow in order. Perhaps of unusual interest is the chapter on Diseases of Uncertain Etiology, in which juvenile rheumatism is divided from adult and senile rheumatism. Juvenile rheumatism, according to the reports, gives an unusual amount of trouble in England, with 1,175 deaths in 1935;

but almost of more importance is the "heart case" or "heart disease" which is left. In the same year, 1935, there were 114,671 deaths from "heart disease," and it is estimated that 40 per cent of these, or approximately 46,000, were the result of juvenile rheumatism. The author recommends 3 months' complete rest in bed for every frank case, followed by 6 months of supervision, a treatment which he feels sure would result in great diminution of after effects.

The author calls special attention to the chapter on Poisonous Gases, which he says may become a matter of immediate concern to doctors as well as the general public. In this he reflects the attitude of European countries and especially, it seems, of England, which is manufacturing gas masks on a stupendous scale, distributing them to the public in enormous numbers, and teaching all, even children, their use.

The book is designed to supply practical information to doctors in practice and to medical students, not for post-graduate students or those working for a Diploma in Public Health. Much as we like the book, we believe it is not one to recommend to medical students, except possibly during their first year. There is a lack of history and the reviewer has long been an advocate of the historical method of teaching. The outstanding feature of the book is its common sense and, what amounts to much the same thing, practical usefulness. Immediately under the name of each disease the causative organism and the period of incubation are given.

The book is written in easy and readable style, very free from errors, and can be commended.

MAZÏCK P. RAVENEL

Take Care of Yourself: A Practical Guide to Health and Beauty—Stressing the Proper Way to Use

and the Prudent Way to Buy Home Remedies and Cosmetics—By Jerome W. Ephraim. New York: Simon and Schuster, 1937. 287 pp. Price, \$2.00.

Certain important aspects of personal health are competently set forth in this book by a layman who is stated by Dr. Logan Clendening in a felicitous foreword to be an "Honest" manufacturer of drugs, cosmetics, and toilet articles. Unlike many of the sensational books that have emanated recently from officials of self-appointed consumers organizations, it is not malicious, misinformed, and meretricious, but is, in general, medically sound and well balanced. Mr. Ephraim writes intelligently and informatively of the care of the teeth, hair, skin, and feet; he also discusses common colds, digestive disturbances, constipation, reducing, vitamins, pain killers, sleep, and antiseptics. Perhaps his best chapter is, seriously, one entitled, "Your Hangover and How Not to Have One." The innumerable purchasers of cosmetics and home remedies will find much of practical value in this interesting book.

JAMES A. TOBEY

Socialized Medicine in the Soviet Union—By Prof. Henry E. Sigerist, M.D. New York: Norton, 1937. 378 pp. Price, \$3.50.

Written frankly from the Marxian viewpoint, Sigerist has given us a book which no one interested in public health can afford to miss. It is not a report but a sociological study: yet it is packed full of facts showing the tremendous progress which has been made in Soviet medicine during the past 20 years. When, following the Great War, the revolution, foreign intervention, drought and famine, the Soviet Union reorganized its medical service, it started from the scratch. During the 20 years from 1913 to 1933 Sigerist tells us that the number of

physicians increased 4 times—from 19,785 to 80,423. In 1936 there were approximately 90,000 physicians and the 1937 health plan called for 107,000. Although this is tremendous, it is insufficient, says Dr. Sigerist. The plan toward which they are working in the Soviet Union calls for 1 doctor per 1,000 of population, which indicates that they are still short 70,000 doctors and 3,000 additional physicians will be needed each year to keep up with the increase in population. The medical schools are rapidly catching up, and although the quality often leaves much to be desired, it too is improving with amazing rapidity.

The author asserts that the Soviet Union was

... the first country that has ever attempted to socialize medicine, the first that ever considered the protection of all the people's health a public function of the State. Much remains to be accomplished in the public health field and no one knows it better than the men who were responsible for the work. I, too, am well aware of present deficiencies in Soviet medicine. . . . There are poor institutions poorly equipped and managed. In Russia as elsewhere, you find bureaucrats and fools and people who like to take the way of least resistance but these shortcomings are seen and admitted freely. They are discussed openly and means and ways are sought to overcome them—not at some uncertain time in the future, but at a definite date according to plan.

Sigerist frankly acknowledges that he has not stressed inadequacies and inefficiencies in his book nor has he wasted time in describing poor institutions.

I have been primarily interested in the principles of Soviet medicine and those positive achievements which represent a permanent gain. . . . My method in this book was like that in the one on American Medicine. There also, I could have written many pages on poor institutions, on the practice of fee-splitting and other dark aspects of American medicine. I omitted them for the same reason because I was convinced that only the positive achievements of

American medicine would in any way enrich the world.

Not only public health officials and medical men but all who are interested in social phenomenon and social experiments will be interested in this book. Every educator in the land, every college professor and college president, and every social worker as well as every health officer, should read this valuable volume.

JOHN A. KINGSBURY

Federal and State Control of Milk Prices—By James A. Tobey, Dr.P.H. Chicago, Ill.: International Association of Milk Dealers, 1937. 42 pp. Price, \$2.00.

This concise volume supplements effectively *The Legal Aspects of Milk Control* by the same author. Members of the dairy industry as well as milk control officers will find useful this discussion of government regulation of milk prices and the production and distribution of milk. The volume reviews the Constitutional status of laws fixing prices and regulating the production and distribution of milk as shown by court decisions.

IRA V. HISCOCK

The Pneumonokonioses (Silicosis). Literature and Laws—Book III—By G. G. Davis, E. M. Salmonsen, and J. L. Earlywine. Chicago: Chicago Medical Press, 1937. 1033 pp. Price, \$8.50.

The third book in the series on the pneumonokonioses covers the period 1915–1936. The two previous books contained references dated from 1556 to 1934 inclusive. The present volume is made up on the same plan as Book I and Book II: a brief abstract of each article issued during the year is given. These abstracts are usually well done and in sufficient detail to indicate the value of the article to the reader. The book is in two parts, with an author and subject index between Part I (Abstracts) and Part II (Laws). The

reviewer again wishes to commend the authors for their work which is so useful to those interested in the subject.

R. R. SAYERS

School Nursing: A Contribution to Health Education—By *Mary Ella Chayer, R.N.* (2nd ed.) New York: Putnam, 1937. 329 pp. Price, \$3.00.

In this second edition, revised and enlarged, Miss Chayer has retained all that was fundamental and helpful in the edition of 1931 and has added much of value accumulated in the intervening years. A new chapter on Rural School Nursing has been added. The author has recognized that the public health nurse should be a health educator and that with special training

in the principles of education she may become a valuable asset in the secondary as well as the elementary schools. The chapter on the preparation of the nurse for school health work indicates the modern trend in nursing education. From a practical standpoint the chapter on the administrative relationships of the nurse with the school should be of considerable help to nurses trying to find themselves, in a complicated situation. The volume is practical in its every chapter. It could be consulted with profit by school executives and public health officials as well as by nurses seeking light on school nursing. The book is supplied with a good working bibliography.

RICHARD A. BOLT

BOOKS RECEIVED

LET'S HELP THE DOCTOR. By M. O'Donovan-Rossa. New York: Devan-Adair Co., 1937. 141 pp. Price, \$1.50.

ATLAS OF SKELETAL MATURATION. By T. Wingate Todd. St. Louis: Mosby, 1937. 202 pp. Price, \$7.50.

APPROVED LABORATORY TECHNIC. By John A. Kolmer and Fred Boener. 2nd ed. New York: Appleton-Century, 1938. 893 pp. Price, \$8.00.

TOXICOLOGY. By William D. McNally. Chicago: Industrial Medicine, 1937. 1022 pp. Price, \$10.00.

THE COLLAPSE THERAPY OF PULMONARY TUBERCULOSIS. By John Alexander. Springfield, Ill.: Thomas, 1937. 705 pp. Price, \$15.00.

NURSES HANDBOOK OF OBSTETRICS. By

Louise Zabriskie. 5th ed. Philadelphia: Lippincott, 1937. 724 pp. Price, \$3.00.

HEALTH. By C. E. Turner and Georgie B. Collins. 3rd ed. New York: Heath, 1937. 231 pp. Price, \$72.

CLEANLINESS AND HEALTH. By C. E. Turner and Georgie B. Collins. 3rd ed. New York: Heath, 1937. 236 pp. Price, \$80.

MILK CONTROL. Governmental Control of the Dairy Industry in the United States. Prepared by the American Municipal Association, Chicago: American Municipal Association, 1937. 49 pp. Price, \$75.

ALCOHOL: ONE MAN'S MEAT. By Edward A. Strecker and Francis T. Chambers. New York: Macmillan, 1938. 230 pp. Price, \$2.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Less Canadian Syphilis? — In Toronto 6,188 persons were reported as under treatment for venereal diseases in May, 1937, a rate of 9.6 per 1,000. Although there was an increase in late cases of syphilis as compared to a similar survey in 1929, there was a 50 per cent decrease in new cases.

BATES, G. A Survey of the Incidence of Venereal Diseases in Toronto in 1937. *Canad. Pub. Health J.* 28, 12:575 (Dec.), 1937.

Wholesale Sewage Disposal—Describing the new New York sewage treatment plant about which every statistician runs into the multiple millions, whether it is dollars of costs, gallons of sewage, or customers served. One gathers that it is an outstanding job excellently done.

BINGER, W. D., and GOULD, R. H. The Wards Island Sewage Plant. *Munic. San.* 8, 12:627 (Dec.), 1937.

Report on Public Relations—At the tenth Annual Conference of the (British) Central Council for Health Education, at which there were over 400 representatives of official and voluntary agencies, the discussion was chiefly concerned with the current national health promotion program, and the possibilities in it for health education to secure better use of existing public health machinery.

CHRYSTAL, G. Public Relations of the Public Health Services. *Pub. Health.* 51, 3 (Supplement) (Dec.), 1937.

About Gonorrhea—In this British experience covering 250 cases, sulfanilamide was found to cure gonorrhea in

most patients with both acute and chronic infections, within a week. The necessary precautionary measures are covered. If cases are rendered non-infectious as promptly, the use of the new drug is a valued addition to the prevention as well as the cure of gonorrhea.

COKKINIS, A. J. Treatment of Gonorrhea with Oral Sulfanilamide. *Brit. M. J.* Nov., 1937, p. 905.

Toward Three Score and Ten—In 1930 the expectation of life at birth for white males was 50 and for females 63 years. The decline in mortality has been most rapid in childhood; above 50 the rates remain unchanged. The current remarkable increase in life expectancy cannot continue in the next generation unless methods are developed for controlling diseases of middle life. The ultimate longevity attainable under present conditions is 70 years. This paper should be studied by every health worker: "must" reading for everyone.

DORN, H. F. The Increase in Average Length of Life. *Pub. Health Rep.* 52, 49: 1753 (Dec. 3), 1937.

Diagnosing Undulant Fever—Discussing the meanings of the skin test, the opsonic and rapid agglutination tests, and cultural methods for brucella infection. The first is the most sensitive. If it is positive, then the second should be performed.

GOULD, S. E., and HUDDLESON, I. F. Diagnostic Methods in Undulant Fever (Brucellosis). *J.A.M.A.* 109, 24:1071 (Dec. 11), 1937.

About Syphilis — Having been brought up on the belief that a repeated positive Wassermann meant syphilis (with easily determined exceptions) and that all syphilis should be treated, this paper raising some question of the value of treatment in the presence of positive Wassermans without other signs of syphilis comes as a great shock. Despite the article, here is one who still believes that syphilis should be treated as long as it exists, providing there are no contraindications.

HINTON, W. A. The Significance of a Positive Blood Test in Syphilis. *New Eng. J. Med.* 217, 25:978 (Dec. 16), 1937.

Allaying Fears of the Asylum—How a state mental hospital assists the surrounding rural communities with ever-present mental hygiene problems is told. Thanks to a continuing educational program and clinic services, 142 of the 776 admissions in 1936 were voluntary, whereas before the program, one or two a month was the rule.

JACKSON, J. A. An Approach to a Rural Mental Health Problem. *Pub. Health Rep.* 52, 49:1777 (Dec. 3), 1937.

Population Problems—This British author observes that the cocksureness with which the contention is made that the poor have more children than the well-to-do, that the agricultural population is more fertile than the industrial, would incline one to assume that statistics prove the assumptions or that they are so obvious that statistics are unneeded. Neither assumption is correct, he says, and tells why. We really ought to have accurate data before we attempt to discuss population trends and the possibility of influencing them.

KUCZYNSKI, R. R. The Future of Our Population. *J. Roy. San. Inst.* 58, 6:356 (Dec.), 1937.

Eugenists Will Be Pleased—Reporting that, in Alberta (Canada),

the work of sterilizing the insane and mentally deficient has gone on quietly, efficiently, and preëminently satisfactorily.

MACLEAN, R. R., and KIBBLEWHITE, M. A. Sexual Sterilization in Alberta. *Canad. Pub. Health J.* 28, 12:587 (Dec.), 1937.

Last Word on Pneumonia—What every health worker should know about the diagnosis and serum treatment of pneumonia. Required reading.

MCCANN, W. S., *et al.* Postgraduate Institute on Pneumonia. *J.A.M.A.* 109, 25:2056 (Dec. 18), 1937.

Despite Inadequate Public Health Measures—Measles death rates have declined, presumably because mothers have been taught to regard the disease seriously and to prevent needless exposure of very young children, and through general improvement in infant nutrition. The author suggests that if immune serum is given, it should be delayed from 5 to 9 days after exposure to modify rather than prevent the attack.

McKHANN, C. F. The Prevention and Modification of Measles. *J.A.M.A.* 109, 25:2034 (Dec. 18), 1937.

When We Were Young—Public health conditions in England a half century ago. These reminiscences by a British M.O.H. are amusing and revealing, and lead to much soul-searching.

ROBINSON, E. S. Forty-four Years of Public Health Work. *Pub. Health.* 51, 3:67 (Dec.), 1937.

Wholesale Health Protection—An absorbing story of the planning, implementing, and organization of the medical and health services for the recent Boy Scout encampment at Washington. Commenting on the whole affair, the author mentions the unusual experience of having 27,000 visitors for 10 days without a single fight, a single

drunk, or case of venereal disease, or a single day spent by a visitor in jail!

SMITH, W. L. Medical Activities at the Boy Scout Jamboree Held in Washington, D. C., June 30-July 9, 1937. *Pub. Health Rep.* 52, 51:1854 (Dec. 17), 1937.

Doubts About Polio Prophylaxis

—In the face of a Toronto epidemic, about 4,500 children received 2 zinc sulphate nasal sprays to protect them against poliomyelitis. Eleven cases occurred while in a control group of 6,300 children 19 cases were reported. The spraying caused no serious complications. The study furnishes no evidence, the authors conclude, that nasal spraying as practised has any protective value against poliomyelitis, and as the

treatment requires the services of otolaryngologists, and cannot be done sufficiently quickly to meet an emergency, it cannot be considered a practical public health procedure. These are disheartening conclusions.

TISDALL, F. F., *et al.* Zinc-Sulphate Nasal Spray in the Prophylaxis of Poliomyelitis. *Canad. Pub. Health J.* 28, 11:523 (Nov.), 1937.

More About Another Tuberculin Test—Tuberculin ointment applied to the skin in a patch test is suggested as a superior substitute for the von Pirquet or Mantoux test.

WOLFF, E., and HURWITZ, S. Further Studies with the Tuberculin Ointment Patch Test. *J.A.M.A.* 109, 25:2042 (Dec. 18), 1937.

ROYAL SANITARY INSTITUTE

THE Royal Sanitary Institute will meet in Portsmouth, England, July 11-16.

The Executive Secretary of the A.P.H.A. desires to know of any Fellows of the Association who plan to be in England during this period.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50th Street, New York, N. Y.

The Department of Civil Service, State of New York, Albany, announces State un-written examinations for which applications should be filed by February 25 as follows:

No. 28. Assistant Director for Oral Hygiene, Division of Maternity, Infancy and Child Hygiene, Department of Health. Appointment expected at \$4,000. Responsibility, to develop a state-wide oral hygiene program. Must be graduates in dentistry and licensed to practise in New York State, with at least

5 years of satisfactory experience and post-graduate study.

No. 29. Chief of Health Education (Health Service), Division of Health and Physical Education, Department of Education. One appointment expected at \$5,000. Duties: To organize and supervise the health service program, conducted by the State in the public schools and teaching institutions. M.D. degree required, with license to practise in New York State.

EMPLOYMENT SERVICE (Cont.)

POSITIONS WANTED

HEALTH OFFICERS

Physician, M.D., Johns Hopkins; public health course at Michigan; experienced in school and city health work, will consider an administrative post in eastern United States. A354

Experienced physician, administrator, epidemiologist, and teacher, now employed, with C.P.H. from Johns Hopkins and 14 years public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., University of Maryland; C.P.H., Johns Hopkins; broad experience in county public health administration, will consider opening of better class. A346

Physician, M.D., Yale, completing M.S.P.H. at Columbia; good clinical background; will consider appointment in child health, epidemiology, or public health administration. A350

Physician, M.D., Western Reserve; short course for health officers, Johns Hopkins; with county and state experience, wishes administrative or epidemiological position; North or West preferred. A349

Physician, M.D., Northwestern University; Dr.P.H., Yale; will consider appointment in general administration, infant welfare, or epidemiology. A300

CHILD HYGIENE

Women physician, M.D., Creighton Medical School, with extensive experience in maternal, infant and child hygiene, and special interest in crippled children's service, desires position in field work. C301

Woman physician, M.D., Yale, Dr.P.H., Yale; experienced in pediatrics and administration of state bureau, will consider attractive opening. C348

SANITARY ENGINEERING

Graduate Sanitary Engineer with service under U. S. Public Health Service and State Departments of Health, especially interested

in filtration plant design and operation and shellfish sanitation, seeks employment. E356

Sanitary Engineer, courses at Rutgers University, with 17 years' experience in design, research, and construction of water and sewage plants, as well as aerial pollution surveys, desires position, preferably research. E321

STATISTICIAN

Young man with 8 years' experience in public health statistics in well known national organization, and degree in Business Administration, now employed, will consider statistical position or combination with office administration. A310

MISCELLANEOUS

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Young woman, M.S., University of Minnesota, wishes position as health education director. An excellent background of experience covers directorship of a state laboratory of hygiene, health education director of a state tuberculosis association, instructor in bacteriology and health education, and executive secretary of a dairy council. M326

Woman with excellent preparation and wide experience in health education field; organization, administration, supervision, and program-making in city, rural and state work. Now employed but would consider good opportunity. \$3,500 minimum. M316

Experienced teacher, B.S., Massachusetts Institute of Technology; graduate courses Harvard School of Public Health, wishes teaching position or will consider statistical or health education opportunity. M353

Young man, at present college teacher of hygiene and physical education and experienced in university medical service, desires position as executive in public or private health organization. M357

NEWS FROM THE FIELD

BETTER CARE FOR MOTHERS AND BABIES

UNDER the auspices of the Children's Bureau of the U. S. Department of Labor, a conference on Better Care for Mothers and Babies was held January 17 and 18 in Washington. More than 400 persons were in attendance from 47 states and the Territories of Hawaii and Alaska, and there were included representatives of 86 coöperating agencies. The American Public Health Association was represented by the President, Dr. A. T. McCormack; Dr. John L. Rice of New York City, and the Executive Secretary.

The conference was addressed by Frances Perkins, Secretary of Labor; Katharine F. Lenroot, Chief of the Children's Bureau; Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service; Josephine Roche, former Assistant Secretary of the Treasury; Dr. Fred L. Adair of Chicago; Dr. Robert L. DeNormandie of Boston; Dr. Martha Eliot of the Children's Bureau; James Roosevelt, Secretary to the President; and other leaders.

That there has been an unnecessary loss of maternal and infant life was made clear by the facts presented, indicating that more than 14,000 women in the United States die from causes connected with childbirth each year, leaving at least 35,000 children motherless. In addition, more than 75,000 infants are stillborn and more than 69,000 infants die during the first month of life. The Findings Committee pointed out that there has been little reduction in the maternal mortality rate during the 22 years for which records are available. It was agreed from the

testimony of several committees of physicians in various parts of the country, after careful evaluation of the causes of death of individual mothers, that from one-half to two-thirds of maternal deaths are preventable. Although the death rate for infants in the first year of life has steadily declined during the last 22 years, there has been little decline in the death rate for the first month of life which accounts for nearly half the total loss of life in the first year.

That there are very important economic aspects of this problem was made evident by the fact that approximately 840,000, or more than one-third of the total births each year, occur in families which are on relief or which have total incomes including home produce of less than \$750 a year. In 1935, 14 per cent of all live births in the United States occurred in the 6 most prosperous states which received 27 per cent of the total income. Fourteen per cent of all live births occurred in the 6 poorest states which received only 5 per cent of the total income.

The conference concluded that, while certain communities through public and private effort have provided a physician's care and hospital care for mother and child at birth when such care cannot be paid for by the family, there has nevertheless been no widespread effort on a national scale to make medical and nursing care at the time of delivery generally available either in the home or in the hospital for mothers in families which cannot obtain such care unaided. A quarter of a million women were delivered in

1936 without the advantage of a physician's care and more than 15,000 had no care except that of the family or neighbors.

The conference concluded that preserving the lives and health of mothers and babies is of such paramount importance to all the people that it fully warrants immediate and concerted national consideration and national action. Urging that better facilities should be provided in medical schools, both for undergraduate and graduate instruction, to medical students, physicians, and nurses, the conference went on to the conclusion that the American standard would demand the supervision of each mother throughout her pregnancy by a qualified local physician aided by a public health nurse, together with care at delivery by the same qualified local physician and a nurse trained and experienced in delivery nursing care. Postpartum and postnatal medical and nursing supervision were regarded as most important, and the provision of facilities for consultation service by obstetricians and pediatricians to aid general practitioners in their care of mothers and babies was concluded to be essential.

With special reference to the public health aspects of this problem it was recommended that public health services both in cities and rural areas be further developed for the conduct of complete service in maternity and for the new-born infant through utilizing available competent service under both public and private auspices, extending and approving the public services when they are not adequate to meet the need. The local community must provide maternal and infant care as needed as a part of its public health responsibility, the state giving leadership, financial assistance, specialized service, and supervision in the development of local services as required, and the federal government to assist the

states through financial support, research, and consultant service.

Specifically it was recommended that Title V, Section 502, of the Social Security Act be amended to authorize a larger sum to be appropriated annually to the states for maternal and child health services with provision that the increased payments to the states should be used for the improvement of maternal care and the care of new-born infants.

The conference concluded that the extent to which this plan can be made a reality will depend upon the desire of the public to be served adequately, upon the leadership of the professional groups in the provision of service of high quality, and upon the development by public agencies in coöperation with private agencies and individuals of a program of education and of medical and nursing care adequate to meet the needs of the various groups in the population.

INDUSTRIAL HYGIENE AND TOXICOLOGY COURSE

THE Department of Chemistry of the University of Pittsburgh, Pittsburgh, Pa., will give a new course on "Industrial Hygiene and Phases of Toxicology," beginning February 9 and consisting of a series of 16 lectures by Emerson Venable,[†] of the Westinghouse Research Laboratory, Pittsburgh, formerly for several years with the Mine Safety Appliances Company studying protective methods and devices.

This is said to be the first course of its kind to be offered primarily to students of science not directly connected with medicine or public health. It is designed to promote knowledge of the medical and pharmacological significance of the materials handled by the average graduate in chemistry.

COURSES IN SYPHILIS

A PROGRAM of postgraduate study in syphilis has been arranged at New York University College of Medicine to extend from February 15 to June 15, 1938. The course is made possible by a grant from the U. S. Public Health Service through the New York State Department of Health.

The training is intended primarily for physicians already working in state and local departments of health, but other physicians may be accepted. The work will be done in the New York University College of Medicine, in the syphilis clinics and wards of Bellevue Hospital, and in the various laboratories and bureaus of the New York City Department of Health devoted to venereal disease study.

Physicians at present engaged in health department work may apply either directly to the office of the dean at the College of Medicine, 477 First Avenue, or through their state health departments. Others should apply directly to the college.

The Health Officer, published by the U. S. Public Health Service, for October 1937, lists similar courses in Massachusetts at Harvard University, in Tennessee at Vanderbilt, in Ohio at Western Reserve, and in California at a university to be selected. A course is under way at Howard University Medical School for Negroes in Washington, D. C., and at the Johns Hopkins School of Hygiene and Public Health, Baltimore. It is stated also that arrangements have been made by the Pennsylvania State Department of Health to offer such a course with the University of Pennsylvania at Philadelphia.

\$61,000,000 FOR HUMAN NEEDS

A \$61,000,000 gift to charity, to be used during 1938 to aid people of 311 cities, was reported to Charles P. Taft, Chairman of the Community

Mobilization for Human Needs, by community chests throughout the United States and Canada.

Coöperative campaigns sponsored by the Mobilization during the last 3 months of 1937 for social and health agencies have been successful in raising 3 per cent more than they did in 1936, according to records of its administrative agency, Community Chests & Councils, Inc. Mr. Taft said:

An increase of 3 per cent in charitable gifts, made in the face of a falling market and disturbed labor conditions, is a triumph of community spirit. . . .

With the results expected from 155 additional chest campaigns—including those still to be held by Boston, Philadelphia, Rochester, and Cincinnati—a total of more than \$83,000,000 is anticipated for the support of community philanthropies in 1938.

This sum will be appropriated during 1938 to about 8,500 local agencies providing such varied services as aid to dependent children and to families in distress, hospitals and home nursing care for the sick, settlements and day nurseries, guidance and character building of youth through clubs and camps.

Fully 9,000,000 contributors, it is estimated, will have added their gifts, large and small, to reach the total.

NEW DIRECTOR OF PUBLIC HEALTH
IN MEXICO

NEWS dispatches under the date of January 4 from Mexico City indicate that Dr. Leonidas Almazan, former Minister from Mexico to Germany, was named Director of Public Health succeeding General Dr. Jose Siurob who has been transferred to the Directorship of the Federal District including Mexico City. The dispatches indicate that Dr. Enrique Hernandez Alvarez has been appointed Secretary of Public Welfare in a post which now has important relationships to the Department of Public Health.

NATIONAL ASSOCIATION OF SANITARIANS

THE National Association of Sanitarians held its annual convention on December 11, 1937, in San Luis Obispo, Calif.

Sanitarians present represented 20 full-time health departments and 16 trainees were present from the Western School of Public Health in session at the University of California. Berkeley; 103 delegates attended the banquet.

Officers elected for 1938 include:

President—Jack C. Baker,† San Diego County Health Department, San Diego, Calif.

First Vice-President—L. D. Spence, San Bernardino County Health Department, San Bernardino, Calif.

Second Vice-President—William V. Butler, Oakland City Health Department, Oakland, Calif.

Treasurer—Charles G. Kahlert, Los Angeles County Health Department, Los Angeles, Calif., and a board of 9 directors, from Arizona, California, Utah, and Washington, was elected.

A resolution was passed authorizing the Board of Directors to publish an official magazine to be known as "The Sanitarian."

CHILI HONORS DR. GEIGER

THE Government of Chili has granted to J. C. Geiger, M.D.,* the decoration "Cruz de Caballero de la Orden del Merito," for good friendship and assistance to Chili and for his excellent work in and outstanding contributions to public health.

DYE PREPARATIONS

DR. George C. Ruhland, Health Officer of the District of Columbia, has announced that "Lash Lure" and similar dye preparations are prohibited from sale, distribution and use in the District of Columbia. Similar prohibitions are in force for New York City and Chicago. The Health Department chemical laboratory reported that an analysis of the sample of

"Lash Lure" shows it to consist of para-phenylene diamine or a closely related compound, and a small amount of magnesium carbonate.

CONNECTICUT CRIPPLED CHILDREN PROGRAM

UNDER the Social Security Act, Connecticut will receive \$60,000 from the federal government to be added to a similar amount appropriated by the last session of the general assembly for the state's crippled children program, it is reported.

The program will include the establishment of 5 permanent diagnostic clinics throughout the state.

SOCIAL HYGIENE MEETING

THE American Social Hygiene Association will hold its Annual Meeting this year in New York City, as a part of the New York Regional Conference which will cover 3 days, February 1, 2, and 3 (Social Hygiene Day). Headquarters will be the Hotel Astor.

SAFETY CAMPAIGN

IT has been announced by the National Safety Council that a \$25,000 contribution to traffic safety has been made.

The Automotive Safety Foundation will use the gift for additional and personal awards in the 1937 National Traffic Safety Contest conducted by the National Safety Council. The contest ended December 31 and prize winning cities and states will be announced early in April.

Twelve police officers and eight traffic engineers will be selected from the prize-winning cities and states in the Council's contest and sent to Northwestern and Harvard Universities for a year's training in traffic safety.

* Fellow A.P.H.A.

† Member A.P.H.A.

MILITARY SURGEONS MEETING

THE next annual meeting of the Association of Military Surgeons will be held at the Mayo Clinic, Rochester, Minn., October 13-15.

The meeting will be held in conjunction with the Medico-Military Inactive Duty Training Unit, which is under the auspices of the Mayo Foundation. This unit is composed of several hundred medical officers, active and reserves, of the Army, Navy, U. S. Public Health Service, National Guard, and Veterans' Administration.

UNIVERSITY OF ILLINOIS BUILDING
READY

THE new building containing the medical and dental laboratories of the University of Illinois has been completed and occupied.

Seven of the 15 floors are devoted to the medical facilities and the rest to the dental clinics. The building connects through corridors with a similar unit entirely occupied by the medical school and with the Illinois Research and Educational Hospital, which supplies the patients and nurses. A cancer clinic is being prepared in the basement, with \$300,000 already appropriated for radium and equipment, it is reported.

David J. Davis, M.D.,[†] is Dean of the Medical School; Frederick B. Noyes, D.D.S., of the Dental School; and Major H. Worthington, M.D., is in charge of the research and educational hospital.

METABOLIZED VITAMIN D MILK

THE Council on Foods of the American Medical Association have voted to accept pasteurized metabolized vitamin D milk and to grant use of the seal of acceptance to licensed dairies that conform to rules and regulations of the council.

Metabolized vitamin D milk is produced under the joint sponsorship of

Standard Brands, Incorporated, and the Wisconsin Alumni Research Foundation. The irradiated dried yeast intended for use in the feeding of cows may be sold by Standard Brands, Incorporated, only to dairymen licensed by the Wisconsin Alumni Research Foundation. The approved feeding schedule is made a part of the license agreement and before a license is issued the dairyman must present a statement from his local health department, medical milk commission, or other official milk control body to the effect that he is responsible, in good standing, and qualified to produce the milk under proper conditions.

The vitamin D content of the milk produced, as shown by repeated bioassays, is not less than 400 units of vitamin D per quart. The requirements and allowable claims for metabolized vitamin D milk are the same as for other types of vitamin D milk containing 400 U.S.P. units of vitamin D per quart.

RHODE ISLAND ASSOCIATION OFFICERS

AT the Third Annual Meeting of the Rhode Island Public Health Association, held January 11, new officers were elected as follows:

President—Albert Vandale, M.D., Pawtucket

First Vice-President — Fenwick Taggart, M.D., East Greenwich

Second Vice-President—George L. Salisbury, M.D.,* North Kingstown

Secretary and Treasurer—Michael J. Nestor, M.D.,[†] Providence

Corresponding Secretary—Morris L. Grover, M.D., M.P.H.,* Providence

Executive Council—C. H. Bryant, Tiverton; James P. O'Brien, M.D.,[†] Woonsocket; Daniel S. Latham, M.D.,[†] Cranston; Edward A. McLaughlin, M.D.,[†] Providence.

KIWANIS HEALTH SERVICE

ACCORDING to the *Journal of the American Medical Association*, the Florida District Convention of Kiwanis

* Fellow A.P.H.A.

† Member A.P.H.A.

International at St. Augustine has adopted a resolution making the creation of full-time health service through the county unit plan and under the supervision of the State Board of Health one of the major projects of Kiwanis. The resolution suggested that the plan be recommended and sponsored before Kiwanis International as a national project.

SKIN IRRITANTS REPORT AVAILABLE

HENRY FIELD SMYTH, M.D., Dr.P.H.,* of the University of Pennsylvania, Philadelphia, has prepared a report representing a combination of the last three Skin Irritants reports presented to the Industrial Hygiene Section, A.P.H.A., and covering a 9 year period from 1926 to 1934, completely indexed by author and subject. Dr. Smyth offers to loan this copy to those interested, provided they are willing to pay postage both ways and will return the copy within two weeks.

BIBLIOGRAPHY ON VOLATILE SOLVENTS

J. J. BLOOMFIELD, B.S.,* Chairman of the Industrial Hygiene Section, A.P.H.A., has announced that the 78 page Bibliography on Volatile Solvents presented at the 66th Annual Meeting in New York City by Henry Field Smyth, M.D., Dr.P.H.,* of the University of Pennsylvania, can now be supplied in limited numbers of copies by the Industrial Hygiene Section of the U. S. Public Health Service. This report includes a review of the literature for 1934-1936, together with an annotated bibliography.

NEGRO STUDENTS' TUBERCULOSIS STUDY

A STUDY of the health services for Negro college students in ten states has been started by Dr. Paul B. Cornely,† director of student health service of Howard University, Washington, D. C. The study, which is being sponsored by the National Tuberculosis Association, will take Dr.

Cornely to Virginia, West Virginia, North Carolina, South Carolina, Georgia, Alabama, Tennessee, Kentucky, Maryland and Pennsylvania.

Coöperating with Dr. Cornely in his study will be the tuberculosis associations, health officers and educators in the states visited.

ORDER OF MERIT AWARDS

THE Order of Merit of Carlos Finlay was recently conferred on the following members of the faculty of Cornell University Medical College, New York, N. Y., as a recognition of their medical and public health services to Cuba:

Dr. Henricus J. Stander
Wilson G. Smillie, M.D.*
Dr. Foster Kennedy
Edgar Mayer, M.D.†
Morton C. Kahn, Ph.D.†

WATER PLANT MANUAL

THE Texas Division of the Southwest Section, American Water Works Association, announces that a manual for the guidance of water plant operators, sponsored by the Section, has been prepared and will be on sale by the middle of February.

This volume will be reviewed in the *American Journal of Public Health*.

INDIANA'S NEW HEALTH UNITS PERMANENT

THE Indiana State Department of Health recently announced that the 4 district health units established during the flood at Princeton, Huntington, New Albany, and Rising Sun have been placed on a permanent basis.

A new district department was set up recently at Bloomington, including Monroe and Brown Counties. Later it is expected that Johnson, Lawrence, and Morgan Counties will be added to this district.

COURSES IN EDUCATION OF THE HANDICAPPED

TEACHERS College, Columbia University, New York, offers for the year 1938-1939 a limited number of scholarships and teaching fellowships for graduates of normal schools and colleges and for teachers now in service in fields of the handicapped who wish to continue their study programs in a combination of courses given at Teachers College.

Scholarship awards may include tuition, maintenance, and cash stipends. The amount of the stipend will vary with the individual case.

Application forms for scholarships and fellowships may be obtained by writing to Professor Merle E. Framp-ton, Teachers College, Columbia University, 525 West 120th Street, New York, N. Y. Applications must be filed not later than May 1, 1938.

CHARLES HERBERT LA WALL

CHARLES Herbert La Wall, Phar.D., Sc.D.,* distinguished pharmacist and chemist, Dean of Pharmacy of the Philadelphia College of Pharmacy and Science and Senior Member of LaWall and Harrisson, Consulting Chemists of Philadelphia, Pa., died December 7, 1937, at the age of 66.

Dr. LaWall was connected with the *United States Dispensatory*, beginning as associate editor in 1909 on the 20th edition and continuing as co-author with Dr. Horatio C. Wood, Jr., upon the 21st, and of the recent 22nd edition of this standard reference work. He likewise served as a co-author of the 7th and 8th editions of *Remington's Practice of Pharmacy* with Dr. E. Fullerton Cook. He wrote the historical volume, *Four Thousand Years of Pharmacy; An Outline History of*

Pharmacy and the Allied Sciences, which has come to be regarded as a standard reference work on chronology of this branch of science.

He was appointed United States Representative on the League of Nations International Committee for Assaying Opium; he received the Remington Medal from the American Pharmaceutical Association in 1927; was President of the American Pharmaceutical Association in 1919, and President of the Pennsylvania Pharmaceutical Association in 1911. He served in a similar capacity to the American Association of Colleges of Pharmacy in 1923, and during the World War was a member of the War Industries Board.

ECONOMIC LOSSES IN PREVENTABLE DISEASE

THE following quotations are taken from Dr. Thomas Parran's address before the Association of Life Insurance Presidents, December 2, 1937:

Sickness and death rates of previous years are inadequate as yardsticks for the present. Rather than to say the health of the nation is good, it is more accurate to say the health of the nation is better than the distressingly high rates of past years. To stand still in public health is to regress. Public health is a dynamic science. It is extending the horizon of knowledge year by year . . . Give us a weapon for combating a new disease and medicine has a responsibility for seeing that it is used.

It is possible, by applying the public health knowledge we now have, to cut down greatly the economic losses caused by the preventable diseases. The monetary saving resulting from the prevention of these causes of illness and death would begin immediately. The accumulation of savings in a generation would be vast. It would amortize the money spent to effect this economy. It is far less expensive to control these diseases than to continue to pay tax money, charity, personal savings, and sound insurance dollars for the needlessly sick and the premature dead.

PERSONALS

Central States

LESLIE V. BURKETT, M.D.,† of Midland, Mich., formerly Health Officer of Midland County, has been appointed Health Officer for Genesee County.

ROBERT C. FARRIER, M.D.,† who recently resigned as Director of the Delta County Health Department with headquarters in Escanaba, Mich., will take charge of the new Illinois State Department of Health district health unit to include East St. Louis, Centerville, Canteen, and Stites, with headquarters in East St. Louis.

DR. THOMAS E. GIBSON, of Flint, Mich., recently resigned as Health Officer of Genesee County to accept a similar position in Eaton County, to succeed DR. JOSEPH W. DAVIS, resigned.

G. HOWARD GOWEN, M.D.,† has resigned as Assistant to the Chief, Division of Communicable Diseases, Illinois State Department of Health, Springfield, Ill., to direct the new public health unit comprising Champaign and Urbana, Ill. The new health district will replace the former separate health activities in the two townships.

DON W. GUDAKUNST, M.D.,* has been appointed Health Commissioner of the State of Michigan, effective January 3. Dr. Gudakunst has served for the past 8 years as Deputy Health Commissioner of the Detroit Department of Health, with which organization he has been associated for the past 14 years. As State Commissioner of Health of Michigan, he succeeds C. C. SLEMONS, M.D.,* of Grand Rapids.

DR. VAUGHN L. HARTMAN, of Medina, Ohio, resigned as Health Commis-

sioner of Medina County recently, to become Assistant Health Commissioner of Cuyahoga County.

DR. WILLIS L. JACOBUS, JR., of Ottawa, Kans., has been appointed Health Commissioner of Franklin County, to fill the unexpired term of his father, the late DR. WILLIS L. JACOBUS.

LORAN E. ORR, M.D.,† formerly of Greenview, Ill., has been appointed Coördinating Epidemiologist to the State Department of Health, Springfield.

DR. JACOB A. PINSKER, of Wichita, Kans., has been appointed Health Officer of Reno County, Kans., succeeding DR. LEE O. FORNEY, who resigned after 19 years to enter private practice.

DR. CHARLES M. STARR, of Larned, Kans., has been appointed Health Officer of Pawnee County.

DR. WILLIAM B. TURNER II, of Wooster, Ohio, has been appointed to succeed DR. EDWARD M. THOMPSON, of Munfordville, Ky., as Health Officer of Hart County, Ky.

Eastern States

ARTHUR H. CUMMINGS, M.D.* formerly at Saranac Lake, N. Y., has been transferred to Binghamton as New York State District Health Officer.

H. BURTON DOUST, M.D., has been appointed Commissioner of Health of Syracuse, N. Y., succeeding GREGORY D. MAHAR, M.D.†

RAYMOND D. FEAR, M.D., DR.P.H.,* Health Officer of Stamford, Conn., has been appointed District Health Officer on the staff of the New York State Department of Health, in charge of the Tompkins County District.

DR. EDWARD E. HALEY, of Buffalo, N. Y., has been appointed Deputy Commissioner of Health and Director of the Division of Communicable Dis-

* Fellow A.P.H.A.

† Member A.P.H.A.

eases in the Buffalo Health Department, succeeding the late DR. CHARLES A. BENTZ.

DR. AUGUSTUS J. HAMBROOK, Troy, N. Y., was recently appointed a member of the New York State Advisory Council on Health and Physical Education in Public Schools, succeeding DR. FLOYD S. WINSLOW, of Rochester.

ERNEST M. MORRIS, A.B., M.D., C.M.,* Commissioner of Health of Fall River, Mass., for 8 years, has resigned to join the staff of the Harvard School of Public Health, Harvard University, Boston, Mass.

DR. FREDERICK F. RUSSELL, Professor of Preventive Medicine and Epidemiology and Hygiene, Harvard University Medical School, Boston, Mass., was recently awarded the Buchanan Medal of the Royal Society of England, for his work in relation to public health problems on behalf of the International Health Division of the Rockefeller Foundation. Dr. Russell was General Director of the Division from 1923 to 1935.

Southern States

HUGH B. COTTRELL, M.D., C.P.H.,† of Indianola, Miss., since 1935 Director of the Sunflower County Health Department, has been appointed as Director of the field unit which supervises the programs of the county health units for the Mississippi State Board of Health.

SAMUEL REED DAMON, Ph.D., became Director of Laboratories for the Alabama State Department of Public Health on January 1. Dr. Damon was graduated from Brown University in 1916 with a Ph.D. degree from the same institution in 1921. Since his graduation he has been connected with the De-

partment of Bacteriology in the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, first as instructor and, since 1927, as Associate Professor.

DR. JULIUS E. DUNN, of Fort Payne, Ala., for 2 years Health Officer of DeKalb County, has been appointed Health Officer of Lauderdale County, with headquarters in Florence.

DR. FORREST S. ETTER, of Bartlesville, Okla., has been appointed Health Superintendent of Washington County.

DR. CHARLES R. GILLESPIE, of Natchez, Miss., Health Officer of Adams County, has been appointed as Director of Health in Sunflower County.

DR. GILES E. HARRIS, of Hugo, Okla., has been appointed Health Superintendent of Choctaw County, to succeed DR. WALTER N. JOHN, of Hugo.

DR. ANDREW HEDMEG, formerly of Lexington, Miss., has been appointed Health Officer of Adams County, with headquarters at Natchez, Miss.

DR. JAMES W. McMURRAY has been appointed Director of the Broward County Health Unit, with headquarters at Fort Lauderdale, Fla., succeeding PAUL G. SHELL, M.D.,† who has entered private practice in Tampa. Dr. McMurray was formerly Director of the Gulf-Calhoun-Franklin unit, with headquarters at Apalachicola.

DR. THOMAS E. MORGAN, Health Officer of Pinellas County, Fla., with headquarters in Clearwater, has been appointed Regional Medical Consultant to the Children's Bureau of the U. S. Department of Labor for the Southeastern District. Dr. Morgan will have his headquarters in Washington, D. C. The Southeastern District includes: District of Columbia, Delaware, Virginia, West Virginia, Georgia, Florida, North Carolina, and South Carolina.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. ORVAL L. PARSONS, of Lawton, Okla., has been appointed Health Superintendent of Comanche County, to succeed DR. LORIN C. KNEE, of Lawton.

EUGENE C. PECK, M.D., M.P.H.,† of Oakland, Md., Health Officer of Garrett County, has been appointed Health Officer in St. Mary's County, the change to take effect when his successor will be named.

RICHARD H. SHRYOCK, PH.D., Professor of History, Duke University, Durham, N. C., recently received the Mayflower Cup awarded by the North Carolina State Literary and Historical Association in Raleigh, for his book "The Development of Modern Medicine," chosen as the "outstanding book by a resident of the state this year."

SAMUEL D. STURKIE, M.D.,† formerly of Oneonta, Ala., has been appointed Health Officer of Chilton County, succeeding JOHN M. KIMMEY, M.D., M.P.H.,† of Clanton, who resigned to become Health Officer of Calhoun County.

DR. EDWARD M. THOMPSON, of Munfordville, Ky., has resigned as Health Officer of Hart County, to take a similar position in Logan County. He will be succeeded by DR. WILLIAM B. TURNER II, of Wooster, Ohio.

Western States

ORVILLE H. BROWN, M.D., PH.D.,† of Phoenix, Ariz., has resigned as Editor of *Southwestern Medicine*.

JAMES S. CULLYFORD, M.D.,† of Denver, Colo., has been appointed Director of the newly created Division of Rural Health Work and Epidemi-

ology of the Colorado State Board of Health.

DR. NORMAN E. MAGNUSSEN, formerly with the Health Department of Seattle, Wash., has been appointed Health Officer of Pierce County.

DR. HOWARD L. McMARTIN, recently appointed Health Officer of the Twin Falls District, has been made head of the Division of Maternal and Child Welfare in the Idaho State Department of Health.

FRANK S. MORRISON, LL.B., has been appointed Director of Vital Statistics of the Colorado State Board of Health.

DR. ROBERT B. STUMP, formerly of Cleveland, has been appointed Health Officer of the Twin Falls, Idaho, Health District, to succeed DR. HOWARD L. McMARTIN.

Canada

ROY B. JENKINS, M.D., D.P.H.,† Lecturer in Public Health at the University of Alberta and Medical Officer of Health of the City of Edmonton, Alta., has resigned to become Chief of the Division of Epidemiology in the federal Department of Pensions and National Health.

GEORGE M. LITTLE, M.D., D.P.H.,† of Red Deer, Alta., has been appointed Health Officer of Edmonton.

DEATH

FRANK WILCOX PINNEO, M.D., of Newark, N. J., Secretary of the Essex County Medical Milk Commission, and Secretary of the Essex County Medical Society for the last 20 years, died November 18. Early in his career he became intimately associated with Henry L. Coit, the originator of certified milk, and devoted himself through the rest of his life to the advancement of the interests of certified milk.

Mental Hygiene and the Health Department*

ALLEN W. FREEMAN, M.D., F.A.P.H.A.

*School of Hygiene and Public Health, The Johns Hopkins
University, Baltimore, Md.*

IT has long been contended that activities for the promotion of mental hygiene should be incorporated into the program of operations of official departments of health. Propaganda to this end has been active and sustained. It is urged, and with truth, that the protection of mental health is as important as the protection of physical health; that mental disease is a large and growing problem of tremendous economic and social importance; and that health departments are the logical and, in fact, the only agencies capable of conducting certain phases of the program. In spite of this vigorous and long continued propaganda, health departments have been slow in undertaking definite programs of activity in mental hygiene. There have been, of course, exceptions, but in general the subject has not actively interested many of our health officers and health workers.

No small part of the difficulty in

securing the incorporation of mental hygiene into the health program is due to the indefiniteness and confusion which surround the term "mental hygiene" itself. When we speak of the prevention of infant mortality, the promotion of maternity hygiene, or the prevention of tuberculosis, speaker and hearer alike have a reasonably clear and uniform conception of what is meant by the terms used. When we speak of mental hygiene, however, we may be considering either the need for improvement in the diagnosis and treatment of frank cases of mental disease, or an argument for broad sociological and economic changes which will reduce the pressure of anxiety or worry of the individual, and thus enable persons to maintain mental health who under existing circumstances break down. Between these extremes, perfectly definite clinical procedures on the one hand, and the broad and wishful thinking in economics and sociology on the other, are to be found a wide variety of ideas and procedures, all of which have the common aim of attempting to reduce the prevalence of mental disease in the

* Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

community and to improve the chances of cure of those persons who may be attacked.

From the standpoint of the health department, therefore, to pick out from this congeries of ideas, hopes, and procedures, those things which are capable of incorporation into the program of a health department, has been by no means easy. Any preventive measure must, before it may be incorporated into the health program, conform to certain fairly well defined criteria. The procedure must first of all be really preventive rather than curative. Our health departments are not yet to the point where they can undertake the administration of purely clinical procedures not definitely preventive in nature. The procedure must be capable of general application, and be effective for the whole population. It must be capable of effective application at a reasonable cost. The total amounts of money available to our health departments are small at best, and the prospects of large additions to those funds are not great. Equally important, our procedures must be capable of application by personnel which is available in sufficient numbers to man the organization required. A public health procedure which can be carried on only by exceptionally gifted personnel, and of the highest qualifications, cannot hope for general application by health departments.

Many of the ideas included in the general term "mental hygiene" conform to those requirements. Mental hygiene is in large part still a matter of improved clinical service to the individual. Early recognition, skillful diagnosis, and effective treatment are by far the most important of the procedures now available. Preventive procedures other than those which depend upon wide economic and social change, are not commonly to be found in mental hygiene programs. Most of the pro-

cedures which have up to now been suggested are highly expensive and are capable of application only to small groups. Therefore, some of the difficulties which have been encountered in promoting the conduct of mental hygiene procedures are to be explained by these facts.

The prevention of mental disease rests on no such simple and well understood principles as those which underlie the prevention of communicable disease or the promotion of maternal and infant hygiene. It has as yet developed no simple and effective administrative technic. If the technics of preventive medicine are to be applied to mental disease, those phases of the problem capable of successful attack by these technics must be selected from the whole body of mental hygiene procedures and special personnel developed for their application.

The question of personnel is highly important. It is too much to expect that psychiatrists, however skilled they may be clinically, will develop these administrative procedures. The technics of public health are not unduly complicated or difficult. They are, however, special; peculiar to the field of preventive medicine. They must be mastered, if effective prevention is to be accomplished, whether the problem of disease be physical or mental. If our health departments are actively to enter the field of mental hygiene, a new type of personnel must be developed, familiar both with psychiatry and with public health methods, and these new workers must develop a new administrative technic.

Surveying the field of mental hygiene with a view to discovering problems capable of successful attack by preventive measures, it is evident that the conduct of purely clinical psychiatric procedures, whether for in-patients or out-patients, is not a task for which our health departments are designed or

organized, and there is no apparent reason why it should be given to them. Whether or not the field nursing activities auxiliary to such clinical services can be carried on by the nursing staff of our health departments, is exceedingly doubtful. All psychiatric experience seems to indicate that such nursing personnel must be highly trained and especially skilled, and that their activities are difficult and time consuming. To expect such new duties of our public health nurses, already heavily overburdened in both the amount and variety of work expected of them, seems out of the question.

It is in our school medical services that we recognize our first need for participation by health departments in mental hygiene activities. The addition of psychological and psychiatric activities to school medical services, where these are under the control of health departments, is highly necessary. The weeding out of the mentally retarded from the regular classes and the early diagnosis of the symptoms of beginning mental disturbances, in children and in teachers alike, is a truly preventive procedure of an importance far greater than the early detection of defects of the eye or ear. It is capable of incorporation into the school health program without difficulty.

It is perhaps in the schools and in infant welfare work that the largest immediate, potential field of usefulness of the health department is to be found. Our infant welfare service as at present organized maintains regular contact between physician and child for a large proportion of the child population in our cities, and in certain rural areas. The importance of the mental hygiene component of child welfare is, of course, undoubted. In our opinion, it is here that the preventive aspects of mental hygiene must be undertaken, if at all, by the department of health. The so-called child guidance clinics, or habit

clinics, represent a difficult, expensive, and not highly successful effort to remedy defects in early mental training. Much of the work of our mental hygiene clinics and hospitals is likewise devoted to an attempt, often unsuccessful, to cure conditions which might have been prevented in the beginning. It would seem highly desirable, therefore, that an effort be made toward the prevention of these conditions before they arise.

This might conceivably be brought about by an increase in the activity of our existing staff of pediatricians and nurses in the habit training for very young children. If every clinic physician were impressed with the importance of the matter and made it a routine part of his work with mothers at the welfare clinic, and if our nurses were sufficiently interested in the subject to assist mothers in the home in the training of children, the desired result might be accomplished. This addition to the existing program of our welfare clinics will not be easy to secure, but if health administrators are genuinely interested, results will undoubtedly come in time.

The alternative procedure of adding a psychiatrist to the staff of the clinic for the purpose of assisting mothers in the training of children, encounters immediately the difficulties of expense and of the fact that personnel is not available at this time for such service. That this service can be made an integral part of the work of child welfare clinics, and that it is welcomed by the mothers to whom it is offered, has already been well demonstrated in an experiment which has been in operation somewhat more than a year in the Eastern Health District in Baltimore.

Another possible field of development is in public health nursing. There is no doubt that the field nurses of our health departments should have sufficient familiarity with elementary psy-

chology to recognize at least marked deviations from the normal in persons encountered by them in their field service, and psychiatric consultation should be available for these cases. No one familiar with circumstances in the field will expect too much of this sort of activity. Public health nurses cannot be expected to know everything or to do everything, and we require too much of them at present. A little emphasis on the psychiatric aspects of their work, however, would probably be of great value to them in the solution of problems that they frequently encounter.

From the standpoint of the local health department, it would seem that a greater interest in the mental hygiene of the child, beginning with the earliest weeks through the service of the welfare clinic and the field nurse and continuing through school life, is a necessary and desirable thing and should be part of the development program of every department of health. The coördination between the mental hygiene clinic and the field public health nurse should likewise be developed.

In state service there should, of course, be close coöperation between the department of health and the department of mental hygiene. The local health department is the proper center for the itinerant mental hygiene clinic, and the field nurse must of necessity be the link between the clinic and the patient in the home. The principal activities of the state department of health will be in promoting this sort of coöperation in county departments of health.

Some question may be raised as to whether or not state mental hygiene clinics should be conducted by state departments of health or by mental hygiene commissions. In general, it would seem, from the standpoint of technical administrative control, that the mental hygiene commission is best adapted to the conduct of field activities in mental hygiene. The desirable relationship is probably not very different from that now prevailing between tuberculosis hospitals and local health departments.

Reviewing the field, therefore, it is evident that the health department's part in mental hygiene is still strictly limited. Within this limited field, however, there are great opportunities for useful service. Extension of the field will probably wait upon the development of personnel specially trained in preventive psychiatry.

The mental hygiene movement has suffered much from its friends and proponents. Their over-enthusiasm and their putting of propaganda so far in advance of procedure, have done much to obscure the very real importance of the subject. The coldness of practically minded health officers to it is not entirely unjustified.

The importance of the subject, the great popular interest which has been aroused in it, and the so urgent need for successful prevention, demand, however, that health officers attack the problem, develop the men and the methods needed, and prevent mental disease to the full extent to which prevention is possible.

Is There an Epidemiology of Mental Disease?*

HENRY B. ELKIND, M.D., F.A.P.H.A.

*Medical Director, Massachusetts Society for Mental Hygiene,
Boston, Mass.*

IT may be uninteresting to introduce the discussion of a subject by considering definitions, but it seems rather necessary to do so in the present instance as the science of epidemiology is not generally considered by those most concerned with it to include mental disease. I have looked over many texts and in none do I find any systematic discussion or treatment of mental disease as an epidemiological topic. In one book, *Epidemics and Crowd Diseases* by Greenwood (1935), there is a passing reference to dancing mania and similar emotional disturbances of crowds which are considered worthy of epidemiological study. The Vaughans in their textbook *Epidemiology and Public Health* (1923) define epidemiology as the science of epidemics, and state that for a disease to be considered of epidemiological concern a necessary criterion is that it be infectious, or at least possibly infectious, and further that the cause of infection be some germ or virus. A reading of Sir William Hamer's *Epidemiology: Old and New* would also lead one to the same way of looking at

epidemiology. A break with the need of requiring infection by germ or virus is made by Greenwood in the text mentioned above. We quote him as follows:

Epidemiology came to mean the study of diseases, any disease, as a mass phenomenon. It differs from the study of disease by a clinician primarily in respect of the unit of investigation. A physician is concerned with, say, typhoid fever from the point of view of the individual patient, to determine from his experience and the results of his examination (a) that the patient is suffering from typhoid fever, (b) how the case is likely to develop—its prognosis, (c) what treatment is likely to give the patient the best chance of recovery. An epidemiologist is concerned with a prevalence of typhoid fever; he wishes to determine the probable course of that prevalence, whether there are likely to be more cases, when the maximum will be reached, what should be done to reduce the prevalence. The physician's unit of study is a single human being, the epidemiologist's unit is not a single human being but an aggregate of human beings, and since it is impossible to hold in the mind distinctly a mass of separate particulars he forms a general picture, an average of what is happening, and works upon that (page 15).

Because of Greenwood's non-insistence upon an infectious *matrices morbi*, he is able to include a whole chapter on cancer. Although it is perhaps the least valuable chapter in the book (because at the time it was written very little of definite epidemiological value about cancer had been deduced), nevertheless it is worthy of note because

* Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937. Only part of this paper as delivered is published in this issue. The remaining part dealing with the discussion and presentation of specific pieces of statistical and epidemiological work in the field of mental disease may be available later.

it means that epidemiology need not be limited to those diseases caused by some form of infectious agent. Greenwood's book, however, has no chapter on mental disease. So far as I have been able to find in the literature, there is no systematic work dealing with this important class of diseases.

My first conception of an epidemiology of mental disease came from Dr. Milton J. Rosenau, formerly Professor of Preventive Medicine and Hygiene at the Harvard Medical School and School of Public Health. When I was a student of his in 1923-1924, I heard him state that there was an epidemiology of mental disease, even though this was not generally recognized. As a matter of fact, in his department at least one worker was giving his full attention to the epidemiological study of mental disease.

The social and economic importance of mental disease warrants its being included in a science of epidemiology. This no one can doubt. Statistics show that more than one-half of all beds devoted to the care and treatment of disease throughout the country are filled by patients suffering from some form of mental disease. This fact alone entitles it to be a prime concern of public health. When we realize that a good part of the population residing outside of hospital walls suffers from some form of mental disease or disorder, this primacy cannot be challenged.

One might ask how has it come about that a factor of such importance to the public health failed to be included in the science of epidemiology. One of the reasons is perhaps that from early days public health departments have dealt with communicable diseases while other branches of government have had the care and treatment of mentally diseased persons. Undoubtedly another reason is the taboo that has surrounded mental diseases, a taboo which has in part resulted from the Christian atti-

tude toward the body-mind problem, the body being the concern of the physician and the mind of the church. Possibly another reason is the fact that it is only recently that psychiatry has been seriously interested in the matter of the control and prevention of mental disease, chiefly through the influence of the modern mental hygiene movement. A further reason may be the confusion which one may note in current psychiatry as to the nature and origin of mental disease.

For the past 20 or 30 years psychiatrists have been divided into various schools differing mainly in their way of looking upon etiology. These may be roughly classified as (1) the organic, (2) the psychological, and (3) the eclectic, this last having characteristics of the first two.

The organic school stresses etiology, with a noxious agent or organic change as being the prime cause of mental disease. The psychological school and to a considerable extent the eclectic school look upon mental disease rather as the various abnormal ways in which human beings react to difficult situations in life. These difficulties may be inheritance in terms of defective germ plasm, or noxious agents such as infectious metabolic and external poisons, or they may be psychic trauma, mental conflicts, trying situations, and the like. Each individual is looked upon as unique, with a personality which is the resultant of a constitution developing in a continuing series of experience from birth to death. Man is a gregarious individual, and one of the risks of life is the hosts of possible trauma coming about from his contact with his fellow men. He is not only a physical being but a feeling and thinking individual. In terms of present-day philosophy he is not to be looked upon as a mere machine reacting mechanically to internal and external stimuli but as an organism capable of creating

new reactions in response to the various stimuli of existence.

Perhaps an example cited here will help to clarify my discussion at this point. Two individuals may have an influenza infection. One has chiefly pulmonary symptoms, together with the usual mental depression and the general aches and pains which go with the disease. The second has as his main symptom-complex the so-called schizophrenic reaction—a special type of abnormal mental picture. I do not need here to enter into a description of this type of reaction, except to state that it represents in terms of the psychiatrist a splitting of the psyche, a bizarre reaction of the individual, resulting from the disintegrating effects of the toxins of the influenza infection upon the brain. For the group of psychiatrists belonging to the organic school, it is enough to note that we have a psychosis, a mental disease with a certain mental picture, the direct result of an influenza infection. For the other two groups of psychiatrists, it is more important to note the particular way in which the individual reacts to this toxic agent, to note the kind of mental picture and behavior that results, the kind of personality he had before the onset of the infection, and, what is most important, how the patient came to behave that way and to develop a psychosis. In other words, the more modern schools of psychiatry are interested in the dynamics of those influences which caused a certain personality to develop a particular psychosis, and the infective agent is only one of the many influences or factors.

Undoubtedly this discussion of the differences in etiological systems may be confusing to the non-psychiatrist. Essentially this situation is not unique to modern psychiatry, as we find something similar in epidemiological discussions of the last decade or two.

Particularly Greenwood and Hamer of England make much of the point that epidemiology until recently suffered considerably from being too exclusively concerned with the significance of the single etiological agent—the bacterium or virus—and neglected what is perhaps the more important contribution of epidemiology—a concern with all of the significant and pertinent etiological factors which cause a disease to appear in a community, including hereditary influences.

The way in which medical men look upon etiology may be simply a matter of temperament; some prefer to be single etiologically-minded while others prefer to be plural etiologically-minded. This latter tendency is fundamental to much of modern psychiatry, even though we are compelled to note a paradox in the acceptance of a new classification of mental disease adopted by the American Psychiatric Association as recently as 1934 which explicitly emphasizes the single noxious agent, or organic pathology, as the main discriminating criterion of disease entities. This more recent classification exhibits this new emphasis more definitely than the first classification approved in 1916.

There is perhaps another reason why mental disease has only recently come to be recognized as a topic of epidemiological study, and that is the fact that practically the only statistics available in the field of mental disease are of hospital population, in contradistinction to statistics from community populations of communicable diseases and the other physical diseases. Statistics of hospital populations are quite apt to suffer from administrative and legal practices which tend to vary from locality to locality as well as in time. This dependence upon hospital statistics leads one to lean too heavily and too exclusively upon the use of proportionate morbidity as the usual type of

statistical analysis, and this our statistical friends state is a dangerous practice when one uses these statistics for the purpose of inference.

When a man dies, there is no question about it, but there may be some question about the disease to which he succumbed. In many instances there is even more question as to what particular ailment a person is suffering from. The death certificate takes pretty good care of the first two categories, while the latter is quite dependent upon the vagaries of the reporting physician. It may be true, however, that because of the nature of the more serious mental diseases, we get a better picture of the incidence of mental disease from hospital statistics because of the necessity of the incarceration of these patients in a hospital for mental diseases. This picture may be found, however, only in those state administrations where the facilities for care and treatment are adequate and where popular opinion and medical coöperation favor the admission of patients to mental hospitals. This means, therefore, that there are only a few states whose statistics are fairly reliable from this point of view. There may also have been suspicion in the minds of some epidemiologists that some of the statistics available in the annual reports of state hospital administrations and particular institutions may not have been properly presented or prepared. The recent work of Dayton in Massachusetts, some of it unpublished, demonstrates this.

I might venture one final reason for the late interest by epidemiologists in mental disease as being that much of the factual material involves more or less intangible concepts, because psychiatry, dealing so much with the mind, must perforce concern itself with subjective experience, which is so difficult for scientific study and analysis. For example, sex in a statistical sense offers

no difficulty at all to the statistician, but the complicated concepts of the development of the libido are perhaps too much and too difficult for him. Another example may be given as follows: The epidemiologist in the field of communicable disease has generally little trouble with the determination of the onset of an attack of disease, but when one comes to the determination of the onset of a case of schizophrenia, it is one thing if one is a Kraepelinian, another if one is a Meyerian, and still another if one adheres to the psychoanalytic school. This difficulty with etiology, however, is not limited to psychiatry. It is to be noted more particularly in the field of chronic physical diseases, such as chronic nephritis, arthritis, cardiac disease, etc.

Up to this point the discussion has been more or less aimed at demonstrating that mental disease is a proper concern of epidemiology and giving reasons to explain why it has only very recently come to be considered worthy of attention by epidemiologists.

The balance of my discussion will cite a few important facts in the history of the epidemiology of mental disease, even though it be a recent and short one. This is done to further the thesis that there is an epidemiology of mental disease by demonstrating that actual work has been and is being done in this field. (A second paper, which may be available later, would do this more definitely.) Before going further I wish to make it plain that I differentiate between administrative statistics and such statistics as have been utilized for a definite epidemiological purpose. The reason for mentioning this is that so much of state hospital statistics are gathered and prepared just with administrative objectives in mind.

It is difficult to state exactly when statistical information was prepared

and made available and studied from an epidemiological point of view. It is my opinion that the best way to answer this question would be to say that the epidemiology of mental disease started in 1916 with the acceptance of the first classification of mental disease adopted by the American Psychiatric Association and the National Committee for Mental Hygiene. The person to be given credit for this pioneer development in the epidemiology of mental disease is Horatio M. Pollock, Statistician of the New York State Hospital Commission. He also became the first Director of the Bureau (later called Department) of Statistics of the National Committee for Mental Hygiene. Dr. Pollock's influence extended still further in connection with the Federal Census as he was largely responsible for the development of that section that deals with mental disease.

From 1916 to about 1928, the State of New York held the foremost position in this field. Of course, here and there isolated writers discussed some forms of mental disease in an epidemiological way, but what is meant here is any systematic, continued attack on the problem. About 1928, Massachusetts, under the leadership and stimulus of the late Dr. George M. Kline, then State Commissioner of Mental Diseases, offered the most elaborate and serious attack on the problem to be noted in this country.

With funds made available by the state and by the Rockefeller Foundation, a very large and competent research statistical department was organized under the direction of Dr. Neil A. Dayton, whose many contributions to the epidemiology of mental disease and defect are well known.

Almost coincident with the development of this work in Massachusetts came somewhat similar attempts, particularly in the State of New York

under the joint auspices of the Statistical Division of the State Department of Mental Hygiene and the New York State Committee on Mental Hygiene of the State Charities Aid Association. This work was directed by Raymond G. Fuller, assisted by Horatio M. Pollock and Benjamin Malzberg. A more intensive investigation in the social factors of schizophrenia was attempted for a period of 7 or 8 years under the auspices of the Boston Psychopathic Hospital and the Massachusetts Society for Mental Hygiene.

The U. S. Public Health Service has also been interested in this field and in conjunction with the National Committee for Mental Hygiene has recently made an organized advance. The stimulus for this most recent development comes from Dr. Walter L. Treadway, Director of the Division of Mental Hygiene of the U. S. Public Health Service.

Possibly the best statistics on mental diseases in this country are now provided by the Massachusetts State Department of Mental Diseases. This department was the first to recognize the urgent necessity of preparing adequate statistics on the resident population. Before that time statistics on mental diseases had been confined to admissions, discharges, and deaths. While this analysis gave an interesting picture of the movement of the population, it overlooked the serious problem of the accumulation of mental patients within our mental hospitals. The Department of Mental Diseases in the *Annual Reports* since 1928 inaugurated another important change. It divided all discharges, deaths, and resident population into first admissions and readmissions. Formerly it had been the uniform custom to divide admissions into first admissions and readmissions, but to group the discharges, the deaths, and the resident population. Thus, if anyone wished to

follow through what had happened to first admissions, for example, he would be blocked by the fact that statistics on this classification were not available in the discharges, deaths, or resident population. Massachusetts, in making this important division, enabled anyone to follow through and determine discharge rates, by age, for example, of all first admissions. These figures, based upon the present age distribution in the resident population plus the discharges and deaths, give ample opportunity for discriminating analyses of first admis-

sions. Owing to their method of division, similar studies can be made on readmissions.

We see then that mental disease is a proper concern of epidemiology from the point of view of contemporary definitions of this science. The past 20 years or so have witnessed an increasing amount of epidemiological knowledge in this class of diseases and it is my opinion that during the next decade or two mental disease will become an important part of epidemiological science.

Achievements in Mental Hygiene and Promising Leads for Further Endeavor^{*}

C. M. HINCKS, M.D.

*General Director, National Committee for Mental Hygiene,
New York, N. Y.*

IN less than 30 years, the term "Mental Hygiene" has been incorporated in our medical vocabulary and has become associated with a wide range of activities, problems, and possibilities that challenge attention. During this comparatively short time a promising beginning has been made in improving diagnostic and therapeutic arrangements for the mentally afflicted, in strengthening training programs for professional workers, in organizing research, in defining spheres of responsibilities for mental health conservation, in gaining a better understanding of the dimensions and significance of mental hygiene tasks, and in the discovery of profitable lines for further endeavor. It is true that many thoughtful men today are prone to refer to mental hygiene as the most backward branch of medical science, but such an appraisal should not blind us to the fact that there is substantial evidence to indicate genuine progress in this field, and that there are splendid opportunities for productive work that will enrich public health, education, and social service.

It may be worth our while to review

briefly some of the activities that have been contributing to mental health conservation and to give consideration to beginning trends that may lead to significant achievements.

The initial efforts in mental hygiene were directed to the improvement of mental hospitals. Through surveys, public education, and the stimulation of larger expenditures for psychiatric services, an impetus was given to the ushering in of a new deal, as it were, to mental hospital psychiatry. Transformations that were effected in connection with many of our public institutions are illustrated by changes that were brought about in a Canadian mental hospital that I have visited annually since 1918.

Twenty years ago this hospital had 800 patients with only 1 physician in charge. There were no trained nurses. Physical restraint and seclusion were common practices. No attempt was made to furnish occupation for the patients. Deadening idleness abetted deterioration. The rehabilitation rate was low. Today this Canadian hospital is staffed by competent psychiatrists and trained nurses. The reception service for early and recoverable cases is housed in a well designed building and has a complement of 1 physician to 90 patients and 1 nurse to 3 patients.

^{*} Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

There are well organized divisions for various therapies—occupation, physical, recreational, hydro, and so on. Out-patient clinics and public educational activities have been organized. Research programs have been fostered, and as a result of such progressive steps there has been a gratifying stepping up of the rehabilitation rate.

Such an improvement of therapeutic services in many centers has been appreciated by the general public and has led to the referral of an increasing number of patients for hospitalization. In this connection it is interesting to note that in 1910 there were 159,096 patients in the state mental hospitals of this country. In 1936, the number rose to 398,006, an increase of 150 per cent although the population of the United States, as a whole, increased by only 40 per cent during this time.

Unquestionably mental hospital services have been improved and extended, but if we consider the United States and Canada as a whole, we discover that the advance has not been along an even front—that there is considerable variation in the degree of excellence of institutions in certain areas as compared with others. This is revealed through a recent study conducted by the National Committee for Mental Hygiene that involved a canvass of the 169 state mental hospitals of the country in reference to 18 standards that reflected their clinical and scientific status. The New England and Atlantic states stood at the top of the list, according to the scheme of rating adopted, and the Southern states at the other extreme furnished a considerable contrast. Of the 169 hospitals, only 47 were adequately organized, staffed, and equipped for the most effective clinical and scientific work; and it was discovered that overcrowding was seriously hampering therapeutic activities in many places. Apparently, 78,000 additional beds are required in the United

States, and Canada is also faced with the need for a marked extension of facilities.

It is evident that the mental hospital situation furnishes a continuing challenge in the mental hygiene field. It is of prime importance that our hospital services be elevated to a high plane of efficiency not only because of their strategic importance in the treatment of the mentally ill but also because of the part they can play in fostering community health programs, research, and prevention.

In a review of mental hygiene progress, reference should be made to the organization of out-patient clinical services throughout the country. The first child guidance clinic was established in 1909. Today there are 153 clinics for children each having a psychiatrist, psychologist, and psychiatric social worker on its staff. The total number of clinics for both children and adults stands at 683 for the United States and 53 for Canada. They are meting out a diagnostic and therapeutic service for more than 12,000 new cases annually.

The actual contribution of clinics to rehabilitation and to prevention is difficult to determine, but there is some available evidence to indicate that they are performing a useful function in this regard.

A striking illustration is furnished by experience in the Oxford District in England where the population is stable—the birth rate equalling the death rate, with immigration and emigration cancelling each other. This district is served by one mental hospital and, since the organization of an affiliated clinic during the war, the admission rate to the hospital has gradually declined although the admission rate to the mental hospitals of England and Wales as a whole has been increasing.

The value of clinics cannot be estimated by reference to mental hospital

statistics alone. They have been an important factor in revealing the mental health needs of communities and in stimulating the development of well rounded programs; and those specializing in child guidance have, in many instances, been training centers for physicians, nurses, parents, teachers, and social workers. They have injected a new and needed note in child rearing by emphasizing the importance of taking into account factors of significance to insure healthy mental growth.

No single phase of mental hygiene progress has been of greater moment than advances, during recent years, in strengthening arrangements for the psychiatric training of physicians. Since 1930, more than half of the 68 accredited medical schools of the United States and Canada have subjected their courses to thorough reviewing and have developed better facilities and procedures for pre-clinical and clinical instruction. In these forward looking schools, emphasis is being placed upon the necessity of taking psychological and situational factors into account in all medical practice. Advances have also been effected in connection with post-graduate training in psychiatry. With the development of a number of well organized and ably staffed centers, the United States is gradually assuming a position of leadership once held by European countries. An impetus was furnished for progress in this direction when 2 years ago there was created the American Board of Psychiatry and Neurology that is demanding high qualifications before certification.

There is no question that the attitude of the medical profession generally toward psychiatry is becoming more hospitable. This is particularly true in reference to pediatricians. Many leaders in this field are today prepared to define pediatrics as concerned with child development—mental as well as physical—and they believe that the pediatri-

cian of the future must be equipped to deal with both the physical and mental hygiene problems of children. If progress is made in this direction preventive work will be markedly strengthened.

Other disciplines in addition to medicine are incorporating mental hygiene in training arrangements. This trend is to be found in the fields of nursing, social work, and theology, and is a promising development because the safeguarding of mental health requires the participation of the various allies of medicine.

The question may be asked if the challenges for research in mental hygiene are being met in a statesmanlike way commensurate with their importance. In answer it should be stated that until recently investigatory work has been unduly neglected and that the comparative backwardness of psychological medicine has been due, in large measure, to the paucity of our knowledge concerning the intrinsic nature of mental disorders and their causation; but there are evidences today that research will receive more attention in the future than has been the case in the past. Encouragement is being provided by great foundations, the Scottish Rite Masons, philanthropic citizens, and a few governments who are making funds available for investigatory purposes. There seems to be no dearth of scientists with well defined programs for research who are eager to prosecute studies in this field. In the state mental hospital services alone, there are 100 well qualified men who desire a greater flexibility of working program to enable them to devote more attention to studies in hand. A recent survey of research activities in dementia praecox revealed that \$650,000 per annum could be put to good account in assisting well conceived projects in this field.

That the fruits of research will be seized upon for practical application in treatment and prevention is indicated

by experience in the testing out of the insulin shock treatment for dementia praecox during the last 12 months. In this time 800 patients have been subjected to this form of treatment in New York State alone, with one hospital reporting a return to the community, in improved state of mental health, of 65 per cent of 81 treated cases.

Whether or not insulin shock proves to have abiding value the point should be stressed that psychiatry today is sensitive to scientific advance and recognizes the need for more and more investigatory effort.

In looking to the future there are many beginning trends that are promising and, if firmly established during the next few years, may lead to genuine progress in health conservation. Four avenues for advance commend themselves particularly to the Canadian National Committee for Mental Hygiene and there will be concerted effort in the Dominion, during the next 10 years, to reach specific objectives in each area of work. Since the objectives have pertinence for the United States as well, I will state them and discuss one in particular that relates to public health.

The first objective entails the placement of treatment arrangements for early and recoverable cases of mental disorders, on as thorough-going a basis as pertains today in general hospital practice for those afflicted with physical disabilities. This will involve the development of intensive treatment units in every Canadian mental hospital, to be staffed with a complement of physicians, nurses, occupational workers, and other personnel, and with appropriate building and plant arrangements to facilitate the creation of a wholesome, cheerful atmosphere for constructive therapy and individualized attention. While costs will necessarily be increased, savings will be effected through the rehabilitation of a larger

proportion of patients than has been the case in the past.

The second objective relates to research. There will be the aim of securing governmental action for the appropriation of 2 per cent of mental hospital budgets for investigatory purposes. Such action will contribute to the placement of psychiatric and mental hygiene research on a sound basis and will furnish an impetus to the nourishing of a scientific spirit among hospital staffs that should be reflected in the improvement of clinical work.

The third objective involves the development of a partnership between health workers and educators for the fostering of mental health conservation among school children. It is assumed that, if the circumstances and conditions for child development during the school years are conducive to healthy growth, a reduction can be effected in the incidence of mental disorders—a reduction of the 4 per cent of school children who today seem destined at some time in their lives to enter mental hospitals as patients, and a reduction of the still larger percentage who can be expected to swell the ranks of the psychoneurotics and misfits.

The fourth objective involves the integration of mental health endeavor into the public health activities of the Dominion, with responsibility for the administration of clinics, the community supervision of maladjusted individuals, the conduct of mental hygiene educational programs for certain professional groups and the general public, and the correlation of all mental health work. At present community mental hygiene programs are loosely organized, with inadequate arrangements for the rehabilitation of paroled patients from mental institutions and of others requiring supervision. There is thus a magnificent opportunity for public health endeavor to right this situation and to place community mental hygiene work

on a basis that will compare favorably with the best programs in the field of tuberculosis.

In many ways this fourth objective of assigning to public health departments the responsibility of developing community mental hygiene programs is the most important of all. We appreciate that success in bringing mental disabilities under control will be dependent in large measure upon the degree of effectiveness of community arrangements for prevention and early treatment, and in facing up to such issues the efforts of a few psychiatrists serving large populations is not enough. There is need for concerted action on the part of health, educational, and social work forces. There is the need for the development of long range comprehensive programs wherein the needs and potential resources of the community are taken into account. Epidemiological studies are a necessary first step in the introduction of constructive efforts wherein the sanitation

of the environment from the mental health point of view will be an objective.

Such a broad gauge program necessitates medical leadership under public health auspices, and it is hoped that during the next 10 years leaders in public health will accept the challenge and will pave the way for the active assumption of responsibility. As one prerequisite in this regard there is entailed the mental hygiene training of public health workers. Without such training there can be no constructive participation by public health forces in mental hygiene work. Our efforts today should be focused therefore on this issue.

In conclusion, may I say that the future for mental hygiene is bright if leaders in public health, education, social welfare, and the supporting sciences will view mental hygiene problems, not as the sole concern of a limited group of specialists, but as a vital challenge in their own field.

Patients, Not Diseases, Are Treated

SIR Auckland Geddes, in an address delivered at the Bicentenary of the Royal Medical Society (reported in the *Edinburgh Medical Journal*, 44:366, 1937, and quoted in *Economics of Radiology*), said:

Time and again, when, in various parts of the world, I have found myself ill or injured and confined to bed, I have been attended by doctors who never even found out that I had any medical training; in fact, they never found out anything about me at all. They were concerned to treat "The Injury" or "The Disease" and not me, the patient;

they were, in short, dealing with a pure abstraction and thinking that they were being very scientific. The more I have seen of life and death, of pain and suffering, the more clearly I have realized that there is never in the real world outside the walls of the Medical School and teaching hospital "A Disease" to be treated; there is never "An Injury" to be dealt with; there is just a sick child, woman, man, to be helped to get well. In short, the real business of clinical medicine is not science. It is, in the case of each sufferer, a personal relationship into which sincerity and medical knowledge are suffused by the physician, and trust and some dependence by the patient.

Relationship of Maternal and Child Health to the General Health Program*

THOMAS PARRAN, M.D., F.A.P.H.A.

Surgeon General, U. S. Public Health Service, Washington, D. C.

THERE is an interdependence between measures directed toward improving maternity and child health and those directed toward improving the general health. There is a similar interdependence between all public health measures and measures designed to promote social welfare and security.

While this Conference is concerned primarily with the health of mothers and children, let us bear in mind that all health problems are family problems, and that family health is one phase of family security. In the mass, family security means social security. Better maternity and child health is or should be among the underlying purposes of any social security measures.

Our specific measures to protect the health of mothers and children count for little if the family income is insufficient to supply nourishing food and decent housing, if the mother's health is undermined by unhealthful sweatshop conditions, or by long hours. Efforts to improve child health count for little if the child must labor in a factory with no opportunity for normal recreation and development. Similarly community protection against impure milk and water, against the acute communicable diseases, against tuberculosis and syphilis and other preventable

diseases which shatter the family well-being, has a direct bearing upon child health on the one hand and upon the security of the family on the other.

For a long time this relationship between poverty and disease has been known. More recently through the National Health Inventory we are able to measure this relationship in exact terms. From these records, it is clear that the one-third of our population ill fed, ill housed, ill clothed also is ill provided with the opportunity for health and life. Illness among persons on relief is 57 per cent higher than among those in comfortable circumstances. The case rate of chronic illness among those on relief is 87 per cent higher than among those with comfortable incomes. In relief families, 1 in every 20 family heads is unable to work because of illness, while among those in comfortable circumstances only 1 in 250 is similarly disabled.

Six million people in the United States are unable to work, attend school, or pursue their usual activities on an average day during the winter months on account of illness, injury, or because of gross physical impairment resulting from disease or accident. Two and one-half million of these are disabled because of chronic disease and permanent impairments. The amount of medical service varies inversely with income. Physicians' services per case of illness were approximately 50 per

* Address before the Children's Bureau Conference on Better Care for Mothers and Babies. Washington, D. C., January 17, 1935.

cent less for relief families than for the higher income group.

By doing what we know how to do to improve the health of this underprivileged group we have the best opportunity of breaking the vicious circle of poverty, ignorance, and disease. Poverty increases disease, which in turn engenders fresh poverty. Until the economists have given us knowledge wherewith to produce and distribute a national income sufficient to provide for the minimum needs of every family, we can at least provide a more equal opportunity for health.

Only a feeble start has been made toward that goal, but I would discuss with you the steps which seem urgent for us as a nation to take in that direction.

A start was made in the evolution of a national health program when the Social Security Act went into effect 2 years ago. Through grants-in-aid to states for maternity and child health, for the care of crippled children, and for general public health work, a real stimulus was given to improved health conditions throughout the country. For the first time it has been possible to appraise the health needs of the several states and communities. The amount of federal aid now invested in national health represents approximately 10 per cent of the total cost. The actual amount of money, less than 13 million dollars, is small in comparison with what government is spending for the end results of health neglect, for the results of untreated disease which load our pension rolls. For example, pensions and care for the syphilitic blind cost 10 million dollars a year. Institutional care of those made insane by syphilis costs another \$31,400,000.

The time seems opportune to expand the federal government's participation in a broad national health program to include: more effective measures for the protection of the health of mothers and

children; the organization throughout the nation of comprehensive measures to cope with those large causes of disease and death for which science has given us weapons of unquestioned power, the provision of the additional hospitals, sanatoria, health centers, and other physical facilities which are necessary and now are lacking in many areas; and better medical services for the medically indigent and the dependent groups of the population.

Such a health program for the prevention of disease and for the better care of those individuals unable to provide it for themselves will bring measurable reduction in future costs of dependency and disability. Without such measures children will need support because their mothers die needlessly in childbirth. Unnecessary deaths from tuberculosis will create additional dependent families. Poorly treated syphilitics will continue to fill our insane asylums and load our relief rolls.

The 12,544 mothers who died as a result of conditions of pregnancy and childbirth in 1935 do not represent the whole of the loss from childbearing. In the past it seems clear that we have underestimated the size and scope of the problem, for there were more than 60,000 babies who died within 2 weeks after birth; there were 77,119 recorded stillbirths. In other words, there occur in the country each year more than 150,000 deaths, 60 per cent of which are due to our mismanagement of the childbearing function.

Economically, children are more valuable now than ever before. The birth rate per 1,000 population continues to decline from 25.1 in 1915 to an estimated 16.5 in 1937. This decline of one-third in the birth rate means that 1,079,000 fewer living babies were born last year than would have been born if the rate had remained at the 1915 level.

We have an ageing population. We have a population which, if present and

past trends continue, will become static within three or four decades. Inevitably our gross death rate will increase. This is to be expected and is not so much a cause of concern as the continued and unnecessarily high death rates in early life and from preventable causes.

The best estimates are to the effect that one-half of the 125,000 babies who died last year were lost unnecessarily. At least one-half of the 12,000 mothers who died in childbirth could have been saved.

An analysis of these maternal and infant deaths shows very uneven rates. In Denver, for instance, a study has shown a death rate among babies in families of less than \$500 annual income to be 168 per 1,000 live births as compared with 30 in families with incomes of more than \$3,000. Deaths from childbirth among Negro women were nearly twice as high as among the white. (There are 9.6 deaths of Negro mothers per 1,000 live births compared with the white rate of 5.4.) Negro babies die at the rate of 88 per 1,000 live births compared with the white rate of 53. Nor has the Negro shared in the health advances of recent years. Since 1920 Negro males between 20 and 50 years of age have suffered a loss in life expectancy of 10 per cent. Among every group which is economically under-privileged, preventable deaths exceeded those among the economically privileged.

For example, in the State of Michigan, no prenatal care is received in 4 of every 10 pregnancies among families on relief, while those in comfortable circumstances get such care in 9 of every 10 pregnancies. Of those on relief, only 26 per cent get adequate prenatal care, while of those in comfortable circumstances, two-thirds get adequate care. Yet medical care in Michigan is above the nation's average.

Approximately 1,000,000 children are

born each year in families on relief or with an annual income of less than \$1,000. Here are found the highest death rates of mothers and of infants; here the least, and the least good medical care. Tax funds should provide the medical, nursing, and hospital costs of childbearing for every woman unable to provide good care for herself. The greatest freedom of choice of the physician should be allowed which is compatible with securing competent service. Such aid would remove an immediate and grave economic barrier to bringing a child into the world.

It would substitute good care under strict professional standards for the haphazard and criminally poor care now being received by so many women. Because they may not have paid the doctor's bill for a preceding childbirth or illness, there frequently is great reluctance on the part of under-privileged women to report to a physician for care early in pregnancy, especially in the rural districts and in those cities where prenatal clinics and free hospital services are not available. Moreover, unless they are entirely destitute and desperate they shrink from going to the welfare officer for aid, because of the stigma surrounding an application for public relief. I propose that public aid for the medical, hospital, and nursing costs of childbearing be put upon the basis of the medical need rather than be measured by the yardstick of a pauper's oath.

Health supervision during infancy and childhood is needed for this same group of the population. In the schools the training of children should include much more attention than we now give to proper nutrition, to full physical development, to the correction of defects, and to training in correct health habits and attitudes.

That tuberculosis is a battle half won should spur us to win the remaining half. The broad averages of 56 deaths

per 100,000 population hide rates among unskilled workers 7 times as high as among the professional groups, and among the colored in the young adult age groups nearly 10 times the white rate. Isolation of active cases in sanatoria has been the keystone of the tuberculosis control movement. Yet in 26 states, there is less than 1 bed per annual death. To provide for the whole country the accepted standard of 2 beds per annual death would require an additional 50,000 beds for the care of the tuberculous. To do the case finding, perform skin tests, make X-rays on positive reactors and on home contacts, and utilize collapse therapy more widely, will require the mobilization of tuberculosis control forces on an unprecedented scale in whole states and sections of the country where now death rates are high and little or no action is being directed against them. In these same areas one finds the most meager financial resources. Substantial federal participation in this campaign is the opportunity of any administration sincerely concerned in helping the under-privileged. By a concerted national effort against tuberculosis there is reason to believe that this disease within a generation can be reduced to the present negligible proportions of typhoid fever.

Syphilis is another disease as serious as tuberculosis and even more devastating in its economic and social effects. Against it we have cheaper methods of case finding, surer methods of arrest and cure, and a method of chemical quarantine which will promptly prevent spread. Yet the battle against syphilis has just started. You who are concerned primarily with the health of mothers and children have neglected for long years this most easily preventable cause of stillbirths, of sickly, deformed infants, of broken homes. The 60,000 babies with congenital syphilis born in this country each year can be

the first major health hazard of the next generation to be removed. To do this we need only to transfer some of the effort and cost now spent in the care of late results of syphilis to the finding of early cases, sources of infection, and contacts, and to providing them with adequate treatment. That this must be largely a public obligation is shown in recent data collected by the Public Health Service. About one-half of syphilis cases now are treated in clinics, the other half in doctors' offices. Of those whom the doctors treat 28 per cent have an annual income of less than \$1,500—insufficient, all will grant, to pay for subsistence for a family plus a complete cure. Opportunity for cure within the means of the patient is a first necessity. Syphilis control is a national problem. A national conference of experts last year recommended a federal expenditure of \$25,000,000—half a battleship a year—which in my opinion would give this country greater security than the same amount spent for armaments. Let us add to this a law in every state requiring freedom from infectious syphilis as a precedent to the issuance of a marriage license. It is devoutly to be hoped also that you obstetricians can improve obstetrical practice in this country to make a blood test early in every pregnancy as routine as is the putting of antiseptic drops into the eyes of every new-born baby.

Only recently and in a few states has pneumonia been accepted as a public health problem. Taking a toll of 100,000 lives each year this disease ranks next to heart disease and cancer as a cause of death. Many of these deaths represent terminal conditions among the aged. How many are due to the pneumococcus we do not know. We do know that a large proportion of the pneumococcic pneumonias are caused by those types of organisms for which we

have an effective curative serum. We do know that the death rate from pneumonia is $3\frac{1}{2}$ times as high among unskilled laborers as among professional groups. We do know that of the deaths under 1 year of age, 20 per cent—1 in 5—are due to respiratory infections, chiefly the pneumonias. We do know that the prompt typing and the use of serum for appropriate cases will cut mortality in half. Yet in nearly every state the basic laboratory facilities to type the disease are not generally available. In all but 2 states, curative sera are not to be had by any except the minority of patients able to pay from \$50 to \$150 for this life-giving remedy. Of every 2 cases treated with serum 1 life can be saved. Is it worth the cost? Here again public provision of these essentials of life are needed on a national scale if we are to reduce the toll of pneumonia deaths.

In the control of cancer we have less exact, less effective tools. Yet before a committee of Congress last year, experts testified that if all cases of cancer received the type of good treatment now available in a few cancer institutes, we could reduce the present toll by at least 20,000 annually. To do this will require a national effort. It will be necessary to establish treatment centers, train expert staffs, provide radiation therapy, and make the services of these centers available to those sufferers unable to pay for the expensive care required.

Persistent, coördinated, systematic research is essential to future cancer control. Congress has recognized this by establishing a National Cancer Institute under my direction with an annual authorized budget of \$700,000 to accomplish this purpose, and to bring the best available knowledge to the help of the present cancer victim. Ways and means of accomplishing these purposes are being worked out with the help of the best minds in the country.

For many other diseases such as malaria and pellagra, we have known but unused methods of prevention.

For others such as acute rheumatic fever, influenza, or cancer, persistent and systematic research is the first need, in order to develop effective methods of control.

In this discussion of our major national health problems and the ways of dealing with them you will recognize an underlying theme: Good treatment, early treatment, means prevention of other cases, and means prevention of death or serious disability for the patient. In fact, one can make the general statement that prompt restoration of an individual to health is an essential part of any complete regime of prevention. Whenever any disease is so widespread in the population, so serious in its effects, so costly in its treatment that the individual unaided cannot deal with it himself, it becomes a public health problem.

Better care during pregnancy and childbirth, protection of the health of children, good nutrition and sound physical development in youth, protection against the acute communicable diseases, control of tuberculosis, syphilis, pneumonia, cancer and other catatrophic diseases, all assume an importance to the community as a whole. The taxpayer now has a financial stake in good health for all. He pays for its neglect in pensions, in relief, and in institutions for the care of the end results of unprevented disease and untreated illness, and in the economic wastes of early, needless death.

I have discussed the measures needed against specific diseases and conditions of national importance. To put these measures into effect we need a reorientation of our public health machinery. We need to build upon the skeletal forces we now have, health organizations in every community able to cope with these new and larger health problems.

We need to coördinate, to integrate the facilities now available—the hospitals, the practising physicians, dentists, nurses, social welfare agencies, in fact, all of the professions and agencies directly concerned with good health. This can be done without any basic change in our present system of medical practice. In fact, much of the public effort will be directed toward making available better tools for the use of the practising physician as a step toward providing necessary facilities for health.

Many areas at present, however, are lacking in the basic facilities requisite to good health. I have referred to our deficiency of tuberculosis hospital beds. May I call attention also to the 18,500,000 of our population living in 1,300 counties with no general (registered) hospital facilities whatever? We do not need a general hospital in every county, but even the minimum standard of 2 beds per 1,000 persons indicates a need for an additional 22,000 beds in rural areas.

Care of the mentally sick is still on a primitive basis in many states. Domiciliary care, little medical attention, no use being made of newer methods of treating general paresis and dementia praecox, is the rule. We need additional beds for mental patients but more than that we need to provide a mental hygiene program to replace the present insane asylum attitude in the care of the mentally sick. Such a change would in future years measurably reduce the load which now burdens all of us.

Many communities lack the laboratory aids to medical practice which modern science indicates are necessary if we are to apply present medical knowledge effectively for all the people. Public funds are needed to provide laboratory services not now available.

Local health departments typically are housed in the basements of city halls or county courthouses. The newer concept of public health can be more

easily put into practice through physical facilities such as health center buildings. Frequently these can be combined with small community hospitals. Many new post offices have been built. With federal aid thousands of new schools have been built. Let us now provide needed hospitals, sanatoria, mental hospitals, and health centers.

Having provided services for those diseases and conditions which are of particular public health importance, and the physical facilities needed for efficient health work, there still remains the lack of general medical care for dependent groups of the population and for those in the marginal economic groups. The evidence is clear that they now get inadequate care. Yet since the time of Queen Elizabeth the idea has been written into the laws that medical care of the indigent is a responsibility of society equal to the responsibility of providing them with food, shelter, and clothing. This idea still lacks application.

We have seen that those on relief have a 50 per cent excess of acute illness and nearly twice the amount of chronic illness experienced by those in the comfortable economic group. Others in the marginal economic groups have the next highest rate and many of them will later be burdens to society because of preventable disease or remedial defects. Many of these illnesses are not curable with present medical knowledge, yet even for them medical care is a humane measure of relief. For a large proportion, medical care will restore health and employability. The returns in reduced relief loads should be enough to pay the cost of the whole job of giving medical care to the dependent groups of the population. Again, a fundamental program seems needed to do this job (with the cost shared by federal, state, and local budgets) which will provide general medical care for the dependent groups of the population.

Our existing structure of social security provides old-age pensions to the needy, unemployment insurance and old-age annuities to soften the impact of job loss and old-age destitution; aid to dependent children and the blind; and the beginnings of a preventive program in public health, maternity and child health, and aid to crippled children. To this base I propose we add a real, nation-wide, result-getting health program which would provide: (1) for all citizens those community measures of sanitation and disease prevention which are necessary if any of us are to be safe; (2) for the underprivileged third of our population, such specific measures of prevention and treatment as good maternity care, child health protection, the control of tuberculosis, syphilis, pneumonia, cancer—conditions which are too important to the nation as a whole for us to permit continued neglect; (3) for areas without them, the physical facilities for good health such as hospitals, sanatoria, and health centers without which no national health program can operate effectively; (4) for those on relief and dependent upon public funds for the other necessities of life, a minimum standard of general medical, dental, nursing, and hospital care.

In my opinion, the major cost of this program should be borne by local and state funds with federal assistance. The health program should be under local operation, adapted to the needs of the community, with state supervision and federal guidance and aid particularly to insure minimum standards and to equalize the financial burden. A pro-

gram such as this costs money, large sums as compared with present expenditures for health, but small as compared with the cost of continued neglect. It will be a wise investment of public funds. It will pay dividends in a more fit citizenship, a less dependent citizenship.

Up to now we have been so busy bailing out the boat that we have neglected to calk up the seams. Let us put first things first in national planning for a more prosperous nation, a more healthful nation, a sounder national economic structure.

A national program of health is essential to any national plan of rehabilitation. It will pay dividends in dollars no less than in human lives. Savings to the nation's economy will be apparent immediately. Savings over the next decade will easily amortise every dollar spent.

May this Conference draw the blueprint for a comprehensive program upon which we can build a sound structure of maternity and child health; and integrate it with the whole composite of a national health program, which is essential for health security, for economic security, for the security of our democratic institutions.

As doctors we have been too closely concerned with gross pathology, too little concerned with positive health—which means much more than freedom from obvious disease. Other nations are making strenuous efforts to produce a generation fit for war. Surely we need no less a generation physically fit for the pursuits of peace.

Essentials of an Effective State Plan and Program of Activities for Flood Sanitation*

C. W. KLASSEN AND
ARTHUR P. MILLER, C.E., F.A.P.H.A.

*Chief Sanitary Engineer, State Department of Health,
Springfield, Ill.; and Sanitary Engineer, U. S. Public
Health Service, New York, N. Y.*

THE location of Illinois in the Ohio River basin places her in a more fortunate position than that of some of her neighbors when it becomes necessary to prepare for flood waters with their resultant destruction, in that a longer period of time must elapse before the river's crest reaches Illinois borders. On the other hand, being at the river's mouth, this state bears the full fury of its flow after being swelled by water from the tributaries which enter it before it joins the Mississippi River at Cairo. In the 1937 flood, forewarnings were available and were heeded, but the unprecedented flows counterbalanced in a measure the good which, under normal flood flows, might have been expected to result from forecasts. However, the ability to anticipate and prepare for a catastrophe such as this is of the greatest importance, even if the time gained for so doing is less than that desired.

Experience is a good teacher but learning lessons at the expense of the public health is too costly. Therefore,

it behooves us to profit by the experiences of others and to avail ourselves of the facts learned in a task of the magnitude facing those in Illinois following this flood. The successes and failures resulting from the execution of the program in this state teach valuable lessons and this paper is prepared for the benefit of those who may find themselves in a parallel situation at some future time. It does not recount incidents, suggest procedures or outline a plan based on hypothetical conditions, but rather on a variety of real occurrences which cover all phases of flood sanitation work.

EXTENT OF FLOOD

The entire gamut of flood problems fell on Illinois early in 1937. There were sudden breaks in levees inundating, within a few hours, municipal areas and large stretches of farm lands, and also there were slow rising waters which gave ample time for the preparation and effecting of some remedial measures. Municipalities many miles away from the Ohio River were flooded by encroaching backwaters. Some towns were completely covered, others

* Read at a Joint Session of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

High Water at Harrisburg

partly so, and one, in its outskirts, leaving a high center as an island. Other states had larger cities with greater populations under the same flood but they had more and better facilities of all kinds with which to meet their emergencies. In Illinois, the many small communities lacking adequate municipal organization, equipment, financial resources, and communication and transportation facilities, presented relatively more difficult problems.

Health and sanitation work could not be concentrated in a small area but had to be spread over a considerable territory. The southern part of Illinois is comparatively flat and low-lying and consequently the river at its crest was able to reach 10 counties and cover 978 square miles. Such an extensive area included many communities and settlements. Unfortunately for flood sanitation operations, this section is lacking in railroad connections and paved highway mileage. As compared to area, the population stricken was small, being only 35,100, but as it is a population of home

owners and renters, many people suffered. Although this section is one in which the incidence of communicable diseases is normally higher than that of the entire state, it is also the general section in which during the last 3 years special emphasis had been given to typhoid fever and diphtheria immunization work.

PERSONNEL

Tornadoes and floods in Illinois in other years provided a certain amount of catastrophe work and experience for the older members of the engineering staff of the State Department of Public Health, but on the whole much of this work had to be done with inexperienced personnel. There were available on the department's staff or on projects with which the department was closely affiliated a group of 29 technical men. This number included 10 who had only recently been placed on duty under the provisions of the Social Security Act; 5 were from the malaria control project then being operated in this southern section of the state; and 3 from the community sanitation project. Un-

fortunately, the district health units formed as a result of the Social Security Act had not reached maximum efficiency and this limited their usefulness, but this emergency confirmed the value of decentralized health work and the suitability of units such as are being organized here to intensify public health work in political subdivisions smaller than a state. The engineers from the malaria control and community sanitation projects were of great help because of their familiarity with this part of the state and their knowledge of the persons who could be of most use in work of this kind. Other departments of the state furnished 6 men and, through the U. S. Public Health Service, 6 men were secured from other states and cities. The Service also had 5 men on field work here for more than a month.

MOBILIZING EQUIPMENT

Early in this strenuous period and before the extent of the flood could be predicted, the department started to mobilize its equipment. For many years it has had emergency chlorination outfits and, because of the close relations existing between the department and plant operators, other types of equipment were made available. The department's mobile laboratory was despatched to the flooded section and later performed good service with an important saving of time on the water supply work. Consideration was also given to publicity and to the preparation of large numbers of various types of instruction sheets and handbills for distribution among the people.

PHASES OF FLOOD SANITATION WORK

Flood work readily falls into two rather distinct phases: that during the period the water is rising to its crest, and that during the recession of those waters and after they have again withdrawn to their usual courses. With the

rising waters, hysteria is inclined to prevail, often influencing the quick decisions frequently needed. Then men are needed who can decide quickly and correctly on the spot what must be done; men who can "keep their feet on the ground" and not give way before all of the suggestions that are made. In the second phase, most of the hysteria has passed but, what is worse, apathy then sets in. While the waters are rising, everyone willingly sacrifices himself to do or give something, but when the mud begins to show there is a tendency for the "heroes of a day" to disappear leaving the slogging work to those more intimately concerned with the public welfare. In those conditions, men are needed who have a driving force behind them and a desire to see a hard job well done, and an endless amount of tact. These qualities should not be ignored in any organization work for they are quite as essential to the success of a scheme as technical ability.

PRE-FLOOD ACTIVITIES

Prior to the time when the Ohio River reached its crest, much effort was devoted to keeping threatened water supply systems in operation, preparing them for inundation and providing temporary facilities which would play a part after the water reached its peak and these plants had been forcibly closed. Eventually 9 public water supplies were affected; 7 being entirely out of service, 1 continuing operation behind 14' of diked-out water, and 1 other operating under the protection of a levee system, but in the early stages this could not be foreseen. The first department engineers were sent to southern Illinois before any municipality was dangerously threatened. To each public water supply where trouble was anticipated, a sanitary engineer was assigned, and emergency sterilization equipment was

installed. All available private wells and cisterns on high ground in areas contiguous to that about to be flooded were treated with chlorinated lime and, after the quality of the water in them had been assured, were placarded with signs reading "Safe Water—This Water is Being Treated and Kept Safe by the Illinois Department of Public Health." In some instances, barrels and tanks of water were maintained. The ready availability of water of good quality in the high areas was found to be an important factor in controlling water-borne illness when the public water supplies were placed out of service or when refugees had to be moved into those areas.

By contact with relief organizations, the field engineers were often able to learn in advance to what point a community was to be evacuated and then to have ready at that point suitable drinking water and other sanitary facilities. If the area to which refugees were to be evacuated was outside of the reporting engineer's territory, the information was relayed to the proper person through the Carbondale field office. This particular activity could have been materially improved, and much valuable time saved if better prearrangements had been made with the Department of Public Health by the agencies removing refugees. This is an extremely important factor in work of this type if the health of the stricken people is to be guarded. During the latter stages of the emergency, better coördination of this work was secured and it proved the value of all efforts to link together refugee movements and the preparation of sanitary work. During this phase, 490 wells, cisterns, barrels, and tanks of drinking water were supervised and maintained in a cleanly condition by the department's engineers.

In some municipalities, in order to locate wells and cisterns which might

be useful when needed, Boy Scouts were employed to canvass areas and locate them. The information they collected was spotted on local maps and utilized at the proper time. It was found that in the chlorination of these small supplies care had to be exercised to eliminate objectionable, chlorinous tastes. If that had not been done, the object of the work would have been defeated because the people would have resorted to other sources of drinking water. A single chlorination of a supply was not found to be sufficient, and constant checking was needed. Wells which were seriously polluted and unsafe for drinking were posted with a sign reading—"Warning: Polluted Water—Do Not Drink."

By anticipating the flooding of a municipal water plant, it was possible to save much equipment. Pump motors were hoisted to high places and other apparatus was made secure. These actions resulted in water works being placed back into operation, after the flood water had gone down, several days earlier than it could have been done otherwise. Another advantage accruing from the assignment of men to areas about to be flooded came through the use of public notices to close off all water lines before leaving property and to give such other assistance as might be helpful after the waters had retired. Even with such warnings, it was found, in many cases, that faucets and taps had been left open and that consequently it was difficult to build up pressures in distribution systems. In one partially inundated municipality with a public water supply, it was necessary to valve off the distribution system in the flooded section.

One unforeseen development in flooded sections of cities was the washing away of small homes and the consequent breaking of their water connections. This reduced pressures and quantities especially when it was im-

possible to cut out the disturbing lines. This was counteracted sometimes by guying these houses to nearby trees or by placing sand bags on the roofs to prevent movement. Where a public water supply had an elevated tank on the system, it was filled to capacity before the town was evacuated and the valve at the base of the tank closed. This stored water then was of great value in rehabilitating the distribution system. Adequate plans of local water lines proved their value in these situations.

In connection with meeting water demands, another problem arose which had not been foreseen. The transfer of refugees into small municipalities placed excessive burdens on both the water and sewage disposal systems there. The population of some of the smaller receiving towns was increased many times above the normal over night, and it was found that the sanitary facilities were not of such capacity as to accommodate this sudden growth. In some cases, refugees had to be moved from one location to another to relieve

these burdens. It is believed that such conditions could have been avoided through more thoughtful planning and closer coördination of the relief agencies with the State Department of Public Health.

One city presented a special problem because a high portion in the center was not flooded but the environs were completely covered, creating a central and inhabited island. From previous experience, it was known that to control water-borne diseases adequately, safe drinking water must be brought to the very door of the consumer. Hence, that was done in this city by securing tank trucks of water at the nearest safe public supply, transferring it to milk cans, at which time it was chlorinated, and then barging it to the unflooded sections of the city and distributing it by truck. Each truck had a definite route much like a milk route, and the citizens were informed through the local radio station that upon arrival of the water truck they would be permitted to secure an adequate quantity (1 gallon per capita per day) for

Barging Safe Drinking Water Into Harrisburg

domestic consumption. Special trucks supplied hospitals, hotels, and other public places. In addition to the importation of water into this community, the total supply was augmented from private wells which were being constantly treated to insure their safety. In order to reduce the use of drinking water, barrels or tanks of untreated water were placed at convenient points throughout the city so people could take it into their homes for flushing toilets.

Besides providing people with safe drinking water, much time was devoted to the care of the refugees. It was soon learned that the Red Cross did not have sufficient technical, supervisory personnel to control sanitation adequately in their far flung camps. Therefore, under an arrangement with them, this work was taken over by the state. Certain groups of camps were assigned to several engineers as their particular responsibility. It thereupon became their duty to see that all sanitary measures essential to safeguarding health were applied and that each camp was maintained free of debris and litter; that toilets and other sanitary devices were kept clean; and that dish-washing methods were as satisfactory as they could be made under the existing conditions. In one instance, the department's engineers supervised the installation of an entirely new water

system for a large tent camp. Although this activity was not foreseen, it turned out to be an important one which continued all through the emergency and until the refugees had been returned to their homes.

PLANNING POST-FLOOD SANITATION MEASURES

A large proportion of the work already described was carried on before the flood waters started to recede. The largest task still remained. Governor Horner foresaw what would be left after the waters went down and, in partial preparation for it, called a conference of the heads of the interested state departments and representatives of the U. S. Public Health Service. Based on the discussions at this meeting a post-flood sanitation program (Chart 1) was devised which was the most complete and extensive ever attempted in Illinois. In this program it was recognized that many agencies would be striving to give aid where it was needed, but that unless they were in some fashion coördinated, effort, time, materials, and supplies would be wasted, and the ones needing help would be that much the losers. In this effort, the U. S. Public Health Service was able to be of service.

The rôle of the Service was thought to include three principal activities: (1) coördinating the efforts of all of

the federal agencies at work with those of the State Department of Public Health, (2) making available to state personnel the results of experiences with other disasters of like nature, and (3) supplying field personnel of the categories desired to augment that of the state. Without some one tying together the plans of the many different groups then in the flood area, success could not have been attained so smoothly. In Chicago, the Service's District Engineer maintained telephonic contact with the field at all times. By remaining there, the health workers in the field had a representative on the job when it was necessary to secure decisions from the Works Progress Administration, the U. S. Army, or some other federal branch whose field representatives could not make them. Speed in this type of work is important and any undue delays ungear the entire operation. He was able to speed up the transmission of supplies and to secure tank cars of safe water which were spotted at the neediest places for subsequent use. In the field, the Service had another engineer (A.P.M.) whose time was devoted to working with the state and to harmonizing the activities of all other federal agencies on this job with those of the state.

As to personnel, the Service was able to supply, through its District Engineer in Chicago, all of the additional help as it was needed. This was made possible by the early creation of a reservoir of persons whose services were promised if a need for them arose. This plan had great flexibility, for it was unnecessary to request help until it was really needed when it was known that sufficient technical assistance was in the background and would be despatched quickly upon call.

ESSENTIALS TO SUCCESSFUL PROGRAM

Four essentials in the conduct of emergency work of this character

might be stated as (1) a centralized headquarters within or adjacent to the stricken area in which the director of the work or his executive shall be ready to respond to inquiries at all times, (2) a decentralized working field force with sufficient supplies and transportation, (3) complete harmony among all agencies working to the same end, and (4) frequent and constant liaison between the working field force, the coordinate agencies, and the director's office. In Illinois, all of these essentials were present and maintained throughout the work with a high degree of efficiency.

At Carbondale, the malaria control project office was ready and waiting when this emergency arose. It was happily located with respect to the territory subject to flooding and to the central offices of other groups; well equipped as to office appurtenances and telephones; and conveniently located as to highways and other transportation facilities. Its equipment was supplemented by a telephone service to the nearest headquarters of the state highway patrol and a short-wave radio sending station, and a short-wave receiving set. As a concentration and distribution point for both personnel and supplies, it was a satisfactory location. Its connection with the highway patrol was very helpful because that group performed yeoman service night and day during the earlier phase. The radio sending and receiving connections were of inestimable value because during the period of extreme high water the only method of communication from some points was via the air. At this office, the authors maintained their headquarters for more than a month. In addition, an executive engineer from the state staff was present all of the time with all necessary stenographic and clerical aides. This office was open 24 hours each day. Here a large wall map built up from U. S. Geological

Survey quadrangle sheets was maintained to show high water levels. This was very helpful in planning field work and predetermining breaks in highway communication. To this office, all incoming personnel was sent to receive instructions and directions before advancing into the flooded zone. All medical activities centered in this office also.

A decentralized field force was secured by establishing 9 temporary districts to cover all of the flooded area (Chart 2). Each had a sanitary engineer in charge and all were responsible to the chief engineer. Eight of these districts were coextensive with 8 counties while the 9th embraced parts of 2 counties. Inasmuch as these temporary district engineers had to secure their labor force through the WPA's local engineer, the headquarters of the sanitary districts were established at the same points as those of the WPA county engineers. This method was very beneficial in that it permitted these two engineers in each county to

work in close harmony. In some cases, the sanitary engineer made his headquarters in the same office as the WPA engineer. In addition to the engineers in charge of the districts, there were others assigned to work under their direction. The number of engineers was varied in each district in accordance with the needs, and as work decreased in volume in an area, surplus assistants were shifted to another district. In general, in each district there were sufficient engineers so that the work could be sub-divided into the 4 special activities shown on Chart 1.

All sub-supervision, labor, materials and most supplies were furnished by the WPA. The CCC established local bases for truck trains throughout the area (see Chart 2) in suitable parks and within truck-travel distance of operations. With these they undertook to furnish transportation until other facilities became available. When trucks were not in use for military purposes, the Illinois National Guard (see

Chart 2) also helped perform the many tasks requiring hauling.

Coördination between all of the agencies engaged in the same task was secured by preparing a plan of work (Chart 1), explaining it to each agency and then through daily visits to them. Each agency was kept informed by a daily memorandum of any new policy and of the status of work.

Liaison was maintained between the field staff, all other agencies, and the directing engineer's office by meetings, telephone, telegrams, and radio. During the first phase of the work—before the flood had reached its crest—every key man in the field would telephone or radio to the field headquarters at a prearranged time and report conditions in his area, receiving at the same time any necessary instructions for the next day. This scheme eliminated any "free lancing" by personnel; kept the program of work under one person's direction; assured complete coverage of affected areas; avoided duplication; and permitted a flexible distribution of men and supplies to meet the needs. This conference generally took place late at night, and before morning the information received from all those reporting had been put into a complete statement and sent to the main office of the State Department of Public Health, the District and Washington offices of the U. S. Public Health Service, and all other agencies in the field such as the Red Cross, WPA, National Guard, Coast Guard, CCC, and U. S. Army. These reports not only gave a résumé of accomplishments to date, but indicated refugee movements and pointed out other matters of use to the coöperating agencies in their fields of activity. Incidentally they made a connected history of activities during the entire period under discussion.

Besides nightly reports, weekly meetings (at night) were held in the field

headquarters. To these came the temporary district engineers and representatives from all other groups. The difficulties of operation such as securing labor, supplies, and equipment, were discussed and settled here. Some controversies were fiery, but to the credit of those involved, all questions were eventually settled to the benefit of the work at hand. This clearing-house of troubles was extremely beneficial. It is difficult to see how such a group of agencies could have worked together without some such common meeting ground.

DETAILED PROGRAM FOR FIELD WORK

A plan for a task of this scope and magnitude must be subject to change to fit unforeseen conditions. Chart 1 shows the organization of the work as it really functioned, including all changes made during its progress. There were four objectives, namely, (1) rehabilitation of public and private water supplies, (2) rehabilitation of sewer systems, and the provision of methods of wastes disposal at homes, (3) cleansing and reconditioning of public buildings, schools, dairies, and milk pasteurization plants to such an extent as to place them in the same condition as they were prior to the flood, and (4) disposal of carcasses and other decaying matter. Cleaning of private homes was held to be the responsibility of the owner, but advice was freely given through various media.

Facing this task it looked appalling in extent. Much pioneer work had to be done and many lessons were learned through successes and failures. One point definitely established was that clean-up work must commence promptly upon the recession of the waters and then follow closely behind them. Publicity was given to the proposed program through the press and the radio. Several times during the work, special phases of the activities were publicized

through the assistance of various co-operating groups; handbills and bulletins of instructions were distributed in isolated areas and were tacked on the outsides of homes or other buildings where they could be readily seen by returning owners; and any other useful means of conveying warnings was used when possible. These instructions emphasized the need for boiling drinking water. In all flooded towns, handbills were tacked at the entrance of the homes, on telephone poles, and at other conspicuous places, warning the citizens that drinking water should be boiled until public approval of the local supply had been given. Brief bulletins explaining the need for care in securing water, about the proper disposal of human wastes, and regarding the use of flooded foodstuffs had been prepared in advance and were used generously.

PLANS MATERIALIZE

Each district functioned much like each other one. Every morning the various crews of WPA men met with their foremen at designated points to receive instructions from the sub-engineer in charge of each activity. CCC trucks were available to move workmen and supplies to that day's destination. Generally, the first task after the water receded was the collection and disposal of carcasses. The smaller ones were usually buried where they were found or close by, but larger ones had to be dragged or hauled to lots where crews of men had been set to work digging trenches. It was important to bury carcasses just as soon as they were freed from the water. Little success was had in burning them, but rendering works collected some. Five hundred large animals—cattle, horses, and mules—and 5,100 small animals—chickens, dogs, cats, and pigs—were handled.

Each temporary district engineer had

received instructions concerning the disposal of bodies of human beings. However, not one was found nor were there any drownings recorded in Illinois as a direct result of high water, though several persons lost their lives while being transported to and from their work in boats.

The rehabilitation of water supplies in the unwatered areas was carried along at the same time as the disposal of the carcasses. Crews of men with foremen were trained for this work. It was found to be impractical to start pumping flood waters from open wells too soon because of the high level of the adjacent ground-water. This was learned, however, only after the walls of several dug wells had collapsed when the water within them had been withdrawn. Just as soon as soil conditions permitted, this work went forward by the use of portable gasoline pumps mounted on trucks for large wells and cisterns, and hand pumps or buckets and ropes for small ones. The aim was to replace a well in a condition comparable with that which existed before the flood, but it was found that the thorough cleansing given to them exceeded that objective. Very few drilled or driven wells were encountered in this area.

In working on dug wells, due regard was given to the physical hazard of entering them and written permission was secured from an owner before any pumping was started if there seemed to be any possibility of the collapse of a nearby structure. Each finished water supply was tagged, giving the date of the work and name of the supervisor handling it, not for the purpose of conveying information on the purity of the water but to avoid duplication. Along with this program, it was possible to carry on some good educational work because frequently owners observed a squad at work and noticed the improvements that were being made. Ap-

Pumping Out a Flooded Well

preciation was expressed by those who were being helped for the type of service which the department was giving. A record was kept of the type, location, and ownership of each well pumped, with the idea that after the emergency had passed considerable useful follow-up work could be done. A total of 5,400 wells and cisterns were pumped, disinfected, and recommendations made for needed physical improvements.

Most of the temporary districts had within them public water supplies which needed reconditioning after the flood waters had returned to their courses. Emergency sources of power had to be secured in some cases to do this and for that purpose tractors and portable gasoline engines proved useful. In one plant, mixing was done by the use of an outboard motor. Disinfection of water mains was essential and for this service the department was fortunate in securing experts from the city of Chicago's Division of Water Purification. Excessively high chlorine residuals were carried in distribution systems for several days. This served

the twofold purpose of sterilizing the mains and of making available to the people a supply of water for washing their homes which had a disinfecting quality. This latter condition had not been planned but many citizens indicated appreciation of water with such a bactericidal effect. After carrying a high chlorine dosage in the mains for several days, it was reduced to normal, and bacteriological examinations were made of samples from the system in the mobile laboratory. If these showed further chlorination necessary, that was done.

With respect to waste disposal facilities, it was originally planned that upon the recession of flood waters, squads of men would provide temporary pits in the rear of residences which had no sewer connections and whose privy buildings had washed away. Instructions regarding the use of such crude facilities were to be tacked on or in each house if the residents had not yet returned. Following these measures it was then proposed to rehabilitate the privies as rapidly as possible. While this plan appeared feasible and appro-

priate, practically it was found to be unworkable. The ground which had been covered with water was so soaked that temporary pits could not be made proof against caving and hence facilities could be provided more quickly by placing reconditioned privy buildings over old pits. Every attempt was made to replace privy structures as they had formerly existed, but there was unquestionably some mixing of buildings. This part of the program was very difficult to administer for many buildings had been entirely washed away or broken up and many pits were left without covering buildings. As a safety measure, pits without buildings were covered with boards or designated as dangerous in some striking way. Due to the failure to secure adequate new material, plans for the construction of new privies on a large scale through the full use of the community sanitation project forces never materialized. However, 3,650 privies were reconditioned and reset.

In municipalities with sewerage systems, cleaning, rodding, and flushing of them presented a separate prob-

lem, but it was successfully surmounted under adequate supervision.

One of the most controversial questions had to do with the unwatering and cleaning of buildings. It was early ruled that this would be undertaken only in buildings which were public and in which people might congregate on occasions. By a rigid application of this rule, this work was in general limited to schools, churches, and hospitals. A total of 127 buildings were cleaned so as to be useable. Removal of mud and debris from streets was assumed to be a local problem and was not included as part of the sanitation program. Promiscuous use of lime was not encouraged, and only one municipality in the area was found to be following this practice. The municipality which had created in its center a high and dry island was struck by a plague of stray animals seeking dry land. No attempt was made by the state to control these as they were not a public health menace at that time. When they became so serious as to be a nuisance, local action took care of them in an expeditious fashion.

The Harrisburg Water Works After 9 Feet of Water Had Withdrawn

When the extent of the flood became evident, emergency orders were given to all municipalities in which refugee camps were located or which were housing refugees that only pasteurized milk should be used. Through the aid of local officials and those engaged in relief work, this action was made generally effective. As a secondary result, the value of milk of this grade in conserving the public health was brought pointedly to the attention of many towns. In Illinois, the control of food-stuffs is a function of the State Department of Agriculture and that department undertook all matters pertaining to damaged foods. However, its field representatives and those of the State Department of Public Health were kept informed of each other's activities and worked in close coöperation. It was found essential for the National Guard to place pickets over rejected food-stuffs consigned to burning or burial; otherwise they were prone to disappear.

An attempt was made through the National Guard to keep people out of damaged homes until they had been restored to a condition not inimical to health, but it was found that the human urge to return home was so great that the plan of control was effective only to a very slight degree. After learning this, provisions were made to care for those wishing to work on their homes so that they could live under habitable conditions.

CONCLUSIONS

Whether the preventive work carried on following a disaster is effective is difficult to prove because of many variables. Furthermore, the history of Illinois contains no flood of the magnitude of that of 1937 and no comparable data are, therefore, available. But the measure of the usefulness of any public health program is the results secured, and it is known that for the flood

period, January 20 to April 3, there were in the flooded section of the state fewer cases of communicable diseases than in any prior and similar period when *normal* conditions obtained. It would seem that the medical and sanitary engineering programs must have played some part in the production of this result. From the engineer's viewpoint, it was gratifying to know that no case of water-borne disease could be traced to the flood. Although one case of typhoid fever was reported, it originated in an unflooded part of the state and the patient was ill upon arrival in the wet section.

Fortunately, the combination of temperature and rainfall which produced this flood is rare, but its rarity is no indication that it will not repeat. Two principles of value for future use made themselves evident in this experience: first, that a practical detailed plan is essential, and second, that such a plan made effective through a scheme of well equipped districts can be made to produce results.

SUMMARY

From January 20 to April 3, 1937, southern Illinois was stricken with a flood which covered 978 square miles and vitally affected over 35,000 people. Pre-flood preparation to protect these people from water-borne diseases and provide the maximum in the way of sanitary surroundings was proved to be possible. A plan for post-flood sanitation involving the use of the district or unit scheme and an effective coördination of all agencies at work in the entire area was followed without undue deviations. The fact that the communicable disease incidence in the area under water and during the period under discussion was less than for a similar period when conditions were normal attests to the successful consummation of the plans.

DISCUSSION

F. C. DUGAN, C.E., F.A.P.H.A.

Chief Sanitary Engineer, State Department of Health, Louisville, Ky.

WE will not attempt in this discussion to cover what should be done by the medical profession, life saving organizations, police, military forces, or relief organizations, but will confine it to the activities in the broad field of sanitation.

DURING THE FLOOD PERIOD

Water Supply—The public water supply is, of course, of paramount importance and no efforts should be withheld to keep it functioning. The area of the community where flood waters have become high and where buildings are being damaged should be cut off from the water supply both for the conserving of water and to prevent contamination of the supply. If in spite of all efforts it is impossible to maintain the public water supply, then arrangements should be immediately made to bring safe water in trucks and tank cars and to use available private sources. Where tank cars or trucks are used they will have to be thoroughly cleaned and sterilized. As a rule, it is advisable to rechlorinate the water brought in in such a manner.

Waste Disposal—Part or all of the sewerage systems will possibly be out of commission, and the immediate construction of sanitary toilets must be undertaken. Arrangements should be made for the collection of garbage and trash, and temporary dumps must be established and maintained.

Milk Supply—In many instances milk pasteurization plants are thrown out of commission and it becomes necessary to bring milk into the city. Pasteurized milk should be brought in in bottles and so distributed where possible. If a pasteurization plant is available, then any milk brought in bulk,

either by tank cars or tank trucks, should be repasteurized.

Refugee Centers—When it becomes necessary to evacuate a large number of people from flood areas, it will be necessary to establish refugee centers to house and feed that part of the population which cannot be cared for in private homes. The sanitary conditions in these refugee centers, the cooking and serving of the food must be carefully supervised, and the medical profession must pay exceptionally close attention to any cases of illness that may occur. It is needless to say that smallpox vaccination and typhoid inoculations should be given.

AFTER THE FLOOD

It is, of course, desirable to return the people to their homes as rapidly as possible, but at the same time efforts should be made to prevent them from returning too soon or else the health officials may face a serious outbreak of disease.

It is therefore necessary immediately to organize cleanup forces, and men experienced in plumbing, electric wiring, and gas systems should be used to make the inspections before permitting people to go back into their homes. Instructions in simple language should be printed and distributed to householders whose homes have been inundated as to how the house should be cleaned and dried out.

Water Supply—If the public water supply has been out of commission, then every effort must be made to rehabilitate the plant rapidly, for a large amount of water will be needed in cleanup. Private water supplies such as wells and cisterns should be cleaned out and then chlorinated.

Sewerage Systems—Steps should be immediately taken to investigate conditions of the sewers and to determine what work will be necessary to put the system if damaged back into commission. Naturally if a sewage treatment plant has been put out of commission, immediate steps should be taken to put the plant in a proper condition. Individual septic tanks will probably have to be cleaned out.

Milk Supply—Milk pasteurization plants which have been inundated should be thoroughly cleaned and given a rigid inspection by competent authorities before being permitted to start operation.

Food and Drugs—In such a catastrophe there is always a large amount of packaged foodstuffs and drugs which have been inundated and also a large amount of fresh or smoked meat and vegetables which have been damaged by flood waters or by lack of refrigeration. Immediate steps should be taken to prevent any of this foodstuff or drugs being sold. In some cases, especially, canned goods, a considerable amount can be salvaged if done under proper supervision. Methods of disposal of such damaged foodstuffs present a definite post-flood problem. Maintenance and policing of dumps are a necessity. Incineration is not always feasible. Burying with other refuse and denaturing with all types of inedible materials offer methods of safe disposal. Some types of foodstuffs can be diverted after denaturing to animal feeding or non-edible uses.

Dead Animals—One of the biggest problems in rural areas is the disposal of dead animals. If there are any rendering or fertilizing plants nearby, they will be of great assistance in the removal of carcasses. Otherwise trenches should be dug and animals buried.

TYPE OF ORGANIZATION NECESSARY

Of course the area affected by the flood will determine in a large measure

the organization of the personnel necessary to handle health activities. The state department of health would naturally be the organization which would be used as the nucleus and its various divisions should be expanded by the addition of temporary employees and voluntary workers. The personnel from the U. S. Public Health Service and other federal agencies and those loaned by other state health departments have always been considered as working under the state health department in the area affected, and during the past emergency this plan worked out very satisfactorily.

Competent sanitary engineers should be given definite areas and they should work in close harmony with the health officer or health officers in their area, making reports to them as well as to the chief engineer of the state department of health. All sanitary engineers, sanitarians, and water laboratory technicians in that area should report directly to the sanitary engineer in charge, and he is responsible for laying out and supervising their work. It is also necessary that sanitary engineers keep in close touch with city officials and relief organizations who can furnish the labor for cleanup purposes.

Food and drug inspection, condemnation and destruction will naturally be handled by the department which has jurisdiction whether it is the state department of health or some other bureau of the state government. The federal food and drug inspectors who will be sent in will report to and work under that department.

In giving a discussion of this topic in a limited time, it is only possible to touch upon the main points of a general plan. In all probability, details will have to be worked out for each area, for much depends upon the character of the area, the population, and the caliber of the man put in charge of that area.

Visual Education for Schools*

PAULINE BROOKS WILLIAMSON, F.A.P.H.A.

Chief, School Health Bureau, Welfare Division, Metropolitan Life Insurance Company, New York, N. Y.

VISUAL education in its broadest sense includes all learning in which seeing is involved. As the sense of sight is the main street, so to speak, over which impressions from the outside world reach the human brain, it is practically impossible to set boundaries for visual education.

The materials for use in learning through seeing are as limitless as the field it covers. Everything that meets the eye in the outside world is a potential architect of new or changed meanings in the inner world of the mind. What one sees may even give the lie to what one has learned in other ways. But although the possibilities of visual education are limitless, in actual practice learning through seeing is limited.

First, mere *seeing* is not learning or observing. Each one of several people looking at the same scene will receive impressions different from those of any other in the group. An artist's observation of a cornfield, for example, will be very different from that of a farmer's son or a city boy.

"Seeing is believing" is an axiom with a corollary, which may be expressed by saying that "seeing is believing what one is prepared to believe."

The visual education of each in-

dividual is limited by the powers of observation and by the particular interest and mental training of each individual. If we wish children really to see certain things they must be given some indication of what to look for, remembering always that what each child sees has been passed through the filter of his personality and can never be identical with what another person sees.

A second limitation placed on the scope of visual education is the *selection* of what is to be seen. There is no question "that visual material is lying all about us waiting to be used." The point is that it is impossible to use all of it to supplement book learning or to motivate desirable practices. Visual material must be selected from the mass for a particular educative purpose, and the purpose is what will determine the use of the material. The sun and moon and stars are visual education materials and how many ways there are of looking at them!

A museum of health for which the children themselves may make or collect the exhibit is a visual education project which has far-reaching possibilities. But before discussing this health museum idea it is well to emphasize the fact that visual education in the field of health presents a far more complex problem than the gathering of material to illustrate factual teaching. It must take into account the

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

appearance and the behavior of all individuals who meet the eyes of children—teachers, administrators, parents, physicians, nurses, specialists, playmates.

This visual education problem is peculiar to the teaching of health. In teaching history, for example, the teacher does not need to have an historical face. The people who have faces capable of sinking a thousand ships do not teach history; they make it. But there is no doubt that in teaching the principles of healthful living it is highly desirable for the teacher to look healthy and to be healthy. She becomes an exhibit of what to look like and how to behave, and of what not to look like and how not to behave, which is more effective than anything she may say. If a teacher tells her students not to put their fingers in their mouths and then absent-mindedly moistens her own fingers with her lips in order to turn the pages of a book, no scientific study will be needed to indicate which has been more effective—what the teacher said or what the students saw her do.

It is not only the appearance and the habits of the teacher and of all other people whom her students admire that she must take into account as visual education materials, but also she must consider the influence of the students' complete environment. This involves the coöperation of many different people of varied interests, professional background, and experience—from the custodian who takes care of the school building to the architect who designed it. It involves also the coöperation of parents, city officials, and all others who are concerned with the child's environment away from school.

There is no question that certain factors in the students' environment may detract from health teaching by giving them eye-witness evidence of the fact that precept and practice may

live in a state of separation if not complete divorce. For example, many a teacher has been obliged to resort to makeshifts in her endeavor to teach children to wash their hands before eating and after toilet because there were no handwashing facilities in the school. The perfect visual education material for teaching the practice of handwashing is the sight of warm running water, soap, and individual towels in the washroom. Lacking these in a school where children eat their lunches of what possible use is it for the teacher to say: "Always wash your hands with warm water and soap before eating." All other visual education materials, such as bacterial cultures from dirty fingers grown by the children themselves on gelatine or agar media, become insignificant if the children are permitted to see *with their own eyes* that the handwashing facilities in school are either lacking or inadequate.

Although doing has more effect on one's health than studying about what should be done, reasonable people insist on knowing why certain health habits are essential. The importance of visual materials in providing concrete imagery is fully recognized, and high standards for the selection and quality of these materials are being attained in certain fields of education, such as art and history, but high standards in the choice of visual materials in the field of health education have not been generally adopted. There is no reason for this situation and you can do much to create a sentiment and a demand for higher standards as well as contribute practical suggestions for improvement.

It is important for health specialists to become familiar with the fine work in visual education that is being done in science, history, and art classes, and to help leading educators to become conscious of the visual materials

in the health education field which are rich in educational value and which are capable of reaching equally high standards of art and workmanship.

To encourage creative ability among young people and at the same time to develop an appreciation of modern health practices, the building of museums of health by children is being recommended. These will require the coöperation of all school departments, creativeness on the part of the students, and continuous growth in the quality of the exhibits in order to maintain high educational standards.

The museum idea for children is not new. Neither is it new to have children make and collect materials for a museum; but a suggestion which has not yet been carried out is that there be a national child health museum made by the children themselves and kept constantly changing and growing by continuous "feeding" from individual children and local communities. In other words, the national museum will grow from the efforts of each child in coöperation with the community as a whole.

There are infinite possibilities in such a project which may begin in a single classroom and spread from one school and community to another. If the exhibits worked out during the coming year warrant the enthusiasm now evidenced by the educators to whom the idea has been broached, it is not difficult to conceive the ultimate establishment of a national museum to which the best models and those of most lasting significance can be sent. However, the starting point should be the formation of local museums of health. In the development of these, creativeness, coöperation, and continuous growth are the important educational features. Working on exhibits for the museum will not only stimulate the student to fresh creation, but will also make him conscious of the constant

state of flux and advance in health matters.

The health museum would capitalize on two interests that are almost universal—(1) collecting materials, and (2) making things. We do not have to create interests for children. They bring them to school. All we need to do is to recognize these interests and give the children an opportunity for expression. As one supervisor states: "When a child comes to school with a loose tooth, there is no reading, writing, or arithmetic which can possibly compete with it in interest, and I consider a loose tooth very important material in school health education." Many children are interested in making a collection of their first teeth as they fall out. A collection of animals' teeth will arouse interest in any school. Various types of shoes may be collected in practically any locality. Little stories about the shoes exhibited may be printed on the labels, giving the dates when they were worn. Collections of different types and sizes and materials of handkerchiefs offer many opportunities for health teaching. An exhibit may be planned to show the evolution of the handkerchief with historical details for the labels such as: "We use square handkerchiefs because Louis XVI issued an edict which read: 'The length of handkerchiefs shall be equal to their width throughout my kingdom.'" An exhibit of the handkerchiefs of today would include soft paper tissues and the cellophane envelopes which are advocated for the bestowal of handkerchiefs both in pockets and in pocketbooks.

In the making of models the child will acquire much valuable health information. The more of this he seeks spontaneously the greater will be its educational value for him. If his bent is historical, he may wish to build a model of a Roman aqueduct; if

modern, he may be interested in showing some phase of the water supply system or the lighting system in his own community. If he likes to read about outstanding men and women who have by scientific research contributed to the advancement of public and personal health, he may wish to dramatize in model form important scenes in their lives. This will give an outlet for artistic as well as constructive ability, and will also acquaint the student with ways of getting needed source material. Making models of aqueducts built in different eras; a series of houses which represent progress in lighting, ventilation, and adaptation to climate; human figures engaged in occupations which illustrate various aspects of preventive medicine and nursing; are all among the possibilities which appeal to the child's dramatic instinct and to his love of construction.

Facility in various crafts, such as wood-carving, weaving, and painting can be displayed to advantage and will give the student a sense of achievement. A project requiring different types of craftsmanship will develop coöperative experience in a class working on the various parts of the model scene.

Before starting to make the models it will often be wise for the children to make observation trips, look up source material, do some historical reading, and collect pictures as guides. The children should be made to feel from the outset that it is their museum, and guidance should be of a directional type and not interfere with their initiative and creativeness.

A child health museum is the type of project in which fathers and mothers will readily become interested. With their interest added to the children's enthusiasm there is the possibility of rousing community action for the advancement of health.

In discussing the practical aspects

of this "museum hobby" with city and rural supervisors on the East and West Coast, in Canada, and in the South, enthusiasm for the idea has been unanimous. Each person consulted had some suggestions to offer based on his particular subject interest, or on the environmental stimuli of his state or community.

As vital as a growing health museum may become in a school program it must not, of course, become an aim in itself. The children's own drinking fountains or individual drinking cups, and their own seating, lighting, and ventilation problems are more important than any museum. They present real life situations. If the museum in any way sidetracks the attention of teacher or students from securing the fundamental tools of healthful living, it becomes a hindrance rather than a help.

There are many good references for people who are interested in the museum project as a method of visual education in the field of health.

In *Fortune*, for April, 1937, an article entitled "American Museum" describes a survey being conducted to answer such questions as: What exhibits attract people most? How long do they stand before any of them? Do they read the labels? Certain definite facts have been deduced from this and similar surveys. A dead-end hall, for instance, will not entice so many people as one open at both ends. A good 70 per cent of visitors observe the right-hand side first. Most people don't like a mechanical display that moves all the time, but if they have something to do with bringing about the motion, the exhibit fascinates them. Most people will not read labels under any circumstances.

There are, of course, a great many more opportunities for visual education in the field of health than the building of working models and ex-

hibits for a museum. A partial list of these would include:

Field trips to dairies, farms, water supply systems, health department laboratories, and other enterprises affecting community health

Photographic and printed material

Charts, diagrams, posters, wall runners, lantern slides, film slides, and microscopical slides made and exhibited in school

Health and safety motion pictures and film strips

Window boxes and aquaria

The use of the microscope in exploring the world of the very small

Dramatizations—for which the students make the costumes and scenery—of scenes in the lives of health heroes, of stirring incidents in man's search for health, and of desirable health practices

The making and dressing of puppets and giving puppet shows

In fact, practically all the devices that are used in school as visual aids in the teaching of the physical, chemical, and biological sciences, the social sciences, English, and mathematics also may be used in the teaching of health as a curriculum subject.

The thing to remember, however, is that health depends principally on doing. If interest in the visual aid or in the knowledge gained by using it is not helpful in establishing healthful living as a way of life, then visual education as a teaching technic has no place in the health education of an individual. It may be taken as a fundamental principle of health education, as it is of all education, that each

child must be given an opportunity to live at his best. The enrichment of the mind and the sound satisfaction of having a reasonable understanding of the meaning of healthful living are certainly commission enough for making health teaching a part of the curriculum. But to make health a part of life, life itself must supply the materials for use in visual health education.

Valuable references on the philosophy of visual education are *Visualizing the Curriculum*,¹ October, 1936, number of *Progressive Education*² which has as its general theme "experience through observation," and the 1937 *Yearbook of the New York Society for the Experimental Study of Education*.³

Accounts of practical experience are given in the Addresses and Proceedings of the National Education Association each year,⁴ and valuable information is found in the *National Visual Education Directory*.⁵

Adaptation of the International List of Causes of Death to Changing Needs of the Medical Profession and Public Health Groups^{*}

HALBERT L. DUNN, M.D., PH.D.

*Chief Statistician for Vital Statistics, Bureau of the Census,
Washington, D. C.*

THE practising physician and public health worker have long been familiar with the processes of collection of death certificates and the published tabulations on cause of death. However, they do not usually appreciate the serious restrictions surrounding and limiting the reliability of the statistical data on cause of death until they become interested in the details concerning a particular disease.

For almost a century the nations of the civilized world have been working toward the development of a uniform system for reporting causes of death. As a result of international coöperation, the *International List of Causes of Death* has been adopted in most of these countries. This list has now undergone several revisions at successive 10 year periods, and will again be revised in the fall of 1938 for the decade 1940-1950.

The Committee on Accuracy of Certified Causes of Death, a sub-committee of the American Public Health

Association, has the duty of inspecting, assimilating, and organizing the various ideas of physicians and health workers as to the changes which should be involved in the revision of the *International List*. Official suggestions for changes to be proposed by the United States for the next decennial revision must be sent to Paris not later than November 1 of this year.

An assumption commonly made by the health worker is that the problem of securing comparable mortality statistics will be solved if satisfactory readjustments can be made in the *International List of Causes of Death*. It is true that such adjustments are essential in order to modernize the List and to bring it into alignment with advances in medicine. However, other factors are involved in the production of statistical comparability of tabulations based upon the rubrics of the List. Among these are such items as: The necessity of keeping statistical comparability over time periods during which the List is being changed; adjustment to the constant growth and change in terminology essential to the expanding field of scientific medicine; correction for inaccuracies in the origi-

^{*} Read before the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

nal notations on cause of death as written by the physician; and the need for a consistent methodology in the selection of the primary cause of death to be tabulated when several causes are noted on the certificate.

PROBLEMS INVOLVED

The fundamental basis for a satisfactory adaptation of the *International List* to the purpose of producing comparable mortality statistics depends upon the accuracy of the cause of death statement on the certificate.

In certain instances, the cause of death is not accurately recorded by the physician due to the necessity of protecting the interests of the patient. One school of thought maintains that a considerable improvement in death information would result if the medical report on the death certificate were made confidential. Such a system exists in Switzerland and Holland. The belief is that if the cause of death information were confidential and used for statistical purposes only, resultant mortality data would be more accurately reported. Experiments were conducted in Westchester County, N. Y., to determine the degree of inaccuracy in the reporting of death from alcoholism and syphilis. It was demonstrated that only about one-half the deaths of these types had been recorded. New York City, at the present time, is considering the possibility of adopting a confidential certificate.

The errors in cause of death due to carelessness on the part of the physician in filling out the death certificate are probably fully as numerous as those arising from his desire for a confidential record. Many times the certificate is written by interns in the hospital, or by physicians uninterested in the accuracy of the facts which they note on the certificate. Correction of carelessness will be purchased only at the cost of constant training in medi-

cal schools and medical societies as to the value of accurate death information. Eternal vigilance is essential in the querying of unsatisfactory terminology.

The struggle for more uniform use in medical terminology is unending. In many instances, terms are either vague or colloquial in nature. In connection with this problem, it is the hope of the Sub-committee on Accuracy of Certified Causes of Death to establish a list of approved terms in the next revision of the *International List*. However, there are many non-approved terms in common use by physicians which are more or less synonymous with approved terms. Sometimes the names of operations or therapies are listed in lieu of a statement as to the cause of death. Yet, even though the particular operation might be stated on the certificate, the cause of death is not necessarily clearly indicated.

The accuracy of the cause of death varies from one certificate to another. In some instances, autopsy, operation, or laboratory findings exist which result in a more accurate knowledge of the true cause of death than when a clinical diagnosis only is available. Moreover, there is considerable variation in cause of death statements due to the great difference in the training of physicians.

The fact of duration of illness was introduced on the death certificate in 1930. This was done that it might be possible to obtain a sequence in disease conditions so that the primary disease could be ascertained with more accuracy. However, at the present time, statements on duration are filled out in only relatively few death certificates. This raises the question, to be considered later, as to what would be the best way to ask the questions on the death certificate in order to elicit a causal sequence when multiple

causes are involved in the same case.

The problem of when and how to query causes of death which are inadequately described is most important if comparability in mortality statistics is to be achieved. In the past, many queries have been sent directly to physicians by the Bureau of the Census. Such queries of necessity were mailed to the doctor from 9 to 12 months after he had filed the certificate. This aggravated him in many instances—and justly so. A query at so late a date that the facts of the case are vague is of little value. An attempt is being made in some states at the present time to take over the query function in the state health department. Such queries can be made by the state within a month or two after the death of the patient. An even better solution is to have some physician in the county, perhaps the county health officer, scan the death certificates before they leave the county in which they are filed. Poor terminology on the part of the physician is more easily corrected if the circumstances surrounding the death are still fresh in his mind.

In addition to these considerations involving the accuracy of the original information, there are other factors affecting the statistical comparability of mortality data which are directly linked with the use of the *International List*. Some of these involve changes in definitions of medical phrases or terms, the establishment of approved terms and their synonyms, and the deletion of colloquialisms or vague phrases which are more or less meaningless. In general, this function is that of the Sub-committee on the Accuracy of Certified Causes of Death. Among other items of this nature which the sub-committee must consider is the fact that many conditions in the *International List* are essentially terms for morbidity rather than mortality, and that such terms should be deleted since these con-

ditions do not add to the risk of dying.

After the terms to be used in the list are selected, a real problem arises as to how they should be classified in order to be of the maximum use to medical and health groups. Physicians investigating a particular cause of death and trying to use statistical facts tabulated according to the *International List* frequently find that the rubrics of the List are not satisfactory for their purposes. Obviously, the number of rubrics in the List must be limited. This means that, in many instances, conditions must be grouped together which are only partially related to each other. In general, the procedure followed is to keep certain titles in the List quite specific in character, while others are miscellaneous. Rubrics for miscellaneous categories pool together rare causes of death and conditions which are vague or relatively meaningless from a statistical standpoint. This pooling of terms under certain statistical rubrics frequently involves the misallocation of certain causes of death so that the information cannot be re-accumulated later in a form desired by the physician. For instance, physicians interested in heart feel that death from rheumatic heart conditions is a recognized entity. Yet at present in the *International List* rheumatic heart conditions are separated into several titles and pooled with other terms listed therein.

The problem of what terms should be included in the index of the *International List* is another controversial problem. At present the index is most complete. It includes not only the more or less approved and commonly used terms, but also unsatisfactory ones. This is due to the fact that, regardless of the amount of querying, there are many death certificates which must be coded in some manner by clerks. Code clerks must be instructed

as to what numbers they should give to unsatisfactory terminology when nothing else is available.

Statisticians have a pet grievance of their own with the *International List*; it involves the change in code numbers at a decennial revision. The widespread use of the List by large statistical organizations in health and insurance means that endless confusion results in the coding of mortality data at these times. Code clerks must be re-trained to the use of new numbers. Tabulating difficulties are many if breaks in the continuity of cause of death data are to be avoided.

Still another major difficulty from the standpoint of obtaining comparability in mortality statistics through the *International List* is the method used in the selection of the primary cause of death. In England and the United States, about one-half of the death certificates contain more than one cause. These causes may be related or totally unrelated to each other. Unless uniform methods are employed in selecting the primary cause of death, the results will lack comparability due to this difference in selection. Some countries, like the United States, use a manual which describes an arbitrary method for choosing the primary cause of death. Others, such as England, are developing a technic which permits the physician to select the primary cause.

In order to obtain some idea of the degree of uniformity existing among nations in the selection of the primary cause, the Bureau of the Census mailed a list of two or more causes of death taken from 1,032 transcripts to 46 nations in 1935. The 1,032 transcripts were copies of actual death certificates. They were selected as representative of problems in the coding of the primary cause of death rather than as a random sample of death certificates.

To date, 15 nations have answered the questionnaire. The percentage

agreements of the 15 nations with the United States and England are tabled. These relative agreements were computed for all 1,032 deaths, and separately for the 89 infant deaths, 70 puerperal, 54 tuberculosis, and 66 cancer deaths in the series.

Except in cancer, where coding similarity is high, the average percentage agreement in the selection of the primary cause of death is in the neighborhood of 60 per cent. Only in puerperal deaths is the average agreement with the United States significantly larger than with England.

The study indicates that international comparability of mortality statistics cannot be achieved without a solution of this problem.

POSSIBLE SOLUTION TO PROBLEMS INVOLVED

A solution of the above problems should make possible a high degree of comparability in mortality statistics, and consequently, an adequate adaptation of the *International List of Causes of Death* to the changing needs of the medical profession and the public health groups.

The possibility of changing the medical notation of the cause of death on the death certificate to a confidential record is being studied in New York City at the present time. It is likely that this feature cannot be introduced into the mortality statistics of the United States since the death certificate is commonly used as a public document. As a matter of fact, it is not at all certain that better statistics would result if the cause of death statement were confidential. No reliable assay of the increased accuracy of the systems in Switzerland and Holland have been made.

Continued advance can be expected in the establishment of approved terminology for causes of death. Specialized medical groups are coöperating at the

present time with the Sub-committee on Accuracy of Certified Causes of Death in the selection of such proposed terms. It has been suggested by the committee that, in the next printing of the *Manual of the International List*, only approved terms will be listed under the rubrics in the tabular part of the List, and that these approved terms be set forth in bold faced type in the index of the *Manual*.

It will be possible in the revision of the *Physician's Pocket Reference*,

dealing with the use of the *International List of Causes of Death*, to introduce not only a complete list of the rubrics but also an index of the approved and commonly used medical terms. By doing this every physician will have available a list of the approved terms. A more homogeneous notation of causes of death should result.

A study is now being undertaken by the Bureau of the Census to separate all medical terms, good and bad, which

are used in the index of the *International List* into 3 groups: those which are approved by the sub-committee as the most desirable; those which are vague in meaning and undesirable; and those in common use by the medical profession but not on the approved list. Each of these 3 groups will be divided in turn into 2 groups—those conditions which can cause death and those which cannot. When this task has been accomplished the statistics from the death certificates of selected areas will be coded accordingly and the percentage frequency under each international statistical rubric, based upon approved and nonapproved terms or upon terms which can or cannot cause death, will be tabulated. As a result of such a study, considerable knowledge will be obtained as to what terms can or cannot be deleted from general usage in notation of cause of death.

A study of a similar nature is planned for 1940, simultaneously with the introduction of the revised *International List*. The plan is to tabulate all of the important alterations in the List. By doing this, tables can be published in 1940 which will be comparable with both the years 1939 and 1941. A knowledge of the relative change produced by shifting certain causes of death from one rubric to another will serve to bridge the gap between the old and the new practice.

Likewise, when medical groups desire to make important changes from time to time in the content of a particular rubric in the List, they can send such suggestions to the Sub-committee on Accuracy of Certified Causes of Death. The Bureau of the Census is willing to assay the more important of the desired breakdowns for an experimental year. It plans to tabulate such statistics and furnish the sub-committee with information on the amount of change involved if the recommendations are followed.

Whenever possible, studies will be conducted on the effect of autopsy information or the existence of laboratory and surgical findings upon the accuracy in diagnosis of cause of death. For instance, at the present time, the Health Department of Chicago is conducting a special study based on autopsy findings in infant mortality. This has resulted in an advance in the knowledge of the true causes of death in the first year of life. The discrepancies which exist in Chicago mortality statistics as tabulated with and without autopsy knowledge have resulted in a better understanding of these mortality facts. It is hoped that studies of this type will be made from time to time by local groups. However, it is not to be expected that the physician will ever have the advantage of autopsy findings available in the majority of deaths. In fact, the physician is frequently not sure of the diagnosis which he records, although he might be reasonably certain that it is one of two or three conditions. The degree of sureness which he feels concerning his diagnosis as to the cause of death should be recorded and introduced in mortality statistics.

Recognizing the difficulties of obtaining accuracy in cause of death data, there is still room for considerable advancement in accuracy if the cause of death questions on the certificate could be asked in such a way as to elicit the best possible answer from the physician. It may seem a relatively simple matter to formulate the questions as to cause of death in a manner that will obtain from the physician the exact information desired. However, the experience of various countries which have studied this question leaves no doubt that it is a complex and difficult problem. The difficulties arise from those cases which involve more than one cause of death.

Realizing the great importance of ac-

in the United States and in England. Differences exist between countries in their methods of determining the primary cause of death which is to be tabulated. Some countries, like the United States, use a *Manual of Joint Causes of Death*, which describes an arbitrary method for choosing the primary cause of death. After considerable experimentation, the English came to the conclusion that the best solution lies in a system mainly based on the certifying doctor's opinion. Authorities in this country feel that such a plan would distort the comparability of our statistics on death.

Perhaps a compromise plan for the United States would be the addition of a question to the cause of death statement on the death certificate, such as: "To which multiple cause should death be assigned?" The physician's

answer to this question could then be tabulated independently from routine death information based on the primary cause of death as selected by the *Manual of Joint Causes of Death*. By this expedient, the results of the physician's opinion could be obtained without interfering with the comparability of statistics on cause of death.

It is doubtful if comparability in the interpretation of death rates can be achieved, *regardless of the method used in the selection of the primary cause of death*, until more real knowledge is obtained about the contributory causes of death. Tabulations of contributory causes would show the extent to which certain diseases are important factors in causing death even though they might not be selected as primary. For instance, the over-all typhoid rate for a community has as much, if not more, significance to the health department than has the death rate in which typhoid fever is listed as the primary cause. The extent to which each disease is associated with other diseases must be known if the true risks of death are to be equated. Even within a given community, the death rate of certain causes of death can be non-comparable in two successive years, not because of the particular disease in question, but due to its association with some contributory cause of death which varies markedly in the successive year. This was particularly true in the influenza epidemic of 1918 for causes of death which took priority over influenza.

In view of these considerations, and after discussion with authorities in a number of European countries, it has been suggested to nations using the complete *International List* that they tabulate multiple causes of death for a trial year or two. Such a tabulation is planned for the deaths of 1936 in the United States. A number of nations—England, Scotland, Denmark,

Switzerland, Canada, Turkey, New Zealand, and Norway—have agreed to produce similar tables. As a consequence, the subject will receive consideration at the International Conference for Revision of the *International List of Causes of Death* in the fall of 1938.

It is likely that ideas concerning mortality will shift considerably when such contributory cause of death tabulations become available. For example, traffic control officers have questioned the fact that accidental deaths are assigned at times as traffic deaths when some other condition, such as pneumonia following the accident, has been the immediate cause of death. The relative unimportance of this criticism is seen in the statistics for Maryland in 1935 which show that 78 per cent of all motor vehicle accidents coded as primary causes had no other contributory cause whatsoever. In the remaining group of motor vehicle accidents, the bulk of the cases, which had contributory conditions, were involved with the following diseases: apoplexy, heart and arterial (50 per cent); pneumonia and respiratory causes of death (27 per cent); septicemia (blood poisoning) (7 per cent); and a miscellaneous group of diseases of one or two cases each (16 per cent). In practically all of these conditions, death would not have resulted if the accident had not initiated the sequence of events leading to death.

CONCLUSION

In the adaptation of the *International List of Causes of Death* to the changing needs of the medical profession and public health groups, the essential goal to be achieved is the production of comparability in mortality statistics.

This cannot result simply by alterations in the *International List*. The major problem also involves the

in the United States and in England.

Differences exist between countries in their methods of determining the primary cause of death which is to be tabulated. Some countries, like the United States, use a *Manual of Joint Causes of Death*, which describes an arbitrary method for choosing the primary cause of death. After considerable experimentation, the English came to the conclusion that the best solu-

tion lies in a system mainly based on the certifying doctor's opinion. Authorities in this country feel that such a plan would distort the comparability of our statistics on death.

Perhaps a compromise plan for the United States would be the addition of a question to the cause of death statement on the death certificate, such as: "To which multiple cause should death be assigned?" The physician's

answer to this question could then be tabulated independently from routine death information based on the primary cause of death as selected by the *Manual of Joint Causes of Death*. By this expedient, the results of the physician's opinion could be obtained without interfering with the comparability of statistics on cause of death.

It is doubtful if comparability in the interpretation of death rates can be achieved, *regardless of the method used in the selection of the primary cause of death*, until more real knowledge is obtained about the contributory causes of death. Tabulations of contributory causes would show the extent to which certain diseases are important factors in causing death even though they might not be selected as primary. For instance, the over-all typhoid rate for a community has as much, if not more, significance to the health department than has the death rate in which typhoid fever is listed as the primary cause. The extent to which each disease is associated with other diseases must be known if the true risks of death are to be equated. Even within a given community, the death rate of certain causes of death can be non-comparable in two successive years, not because of the particular disease in question, but due to its association with some contributory cause of death which varies markedly in the successive year. This was particularly true in the influenza epidemic of 1918 for causes of death which took priority over influenza.

In view of these considerations, and after discussion with authorities in a number of European countries, it has been suggested to nations using the complete *International List* that they tabulate multiple causes of death for a trial year or two. Such a tabulation is planned for the deaths of 1936 in the United States. A number of nations—England, Scotland, Denmark,

Switzerland, Canada, Turkey, New Zealand, and Norway—have agreed to produce similar tables. As a consequence, the subject will receive consideration at the International Conference for Revision of the *International List of Causes of Death* in the fall of 1938.

It is likely that ideas concerning mortality will shift considerably when such contributory cause of death tabulations become available. For example, traffic control officers have questioned the fact that accidental deaths are assigned at times as traffic deaths when some other condition, such as pneumonia following the accident, has been the immediate cause of death. The relative unimportance of this criticism is seen in the statistics for Maryland in 1935 which show that 78 per cent of all motor vehicle accidents coded as primary causes had no other contributory cause whatsoever. In the remaining group of motor vehicle accidents, the bulk of the cases, which had contributory conditions, were involved with the following diseases: apoplexy, heart and arterial (50 per cent); pneumonia and respiratory causes of death (27 per cent); septicemia (blood poisoning) (7 per cent); and a miscellaneous group of diseases of one or two cases each (16 per cent). In practically all of these conditions, death would not have resulted if the accident had not initiated the sequence of events leading to death.

CONCLUSION

In the adaptation of the *International List of Causes of Death* to the changing needs of the medical profession and public health groups, the essential goal to be achieved is the production of comparability in mortality statistics.

This cannot result simply by alterations in the *International List*. The major problem also involves the

methods of collecting the data and the stimulation of accuracy in the recorded data. Suggestions are made in this

paper by which some of the factors affecting statistical comparability can be evaluated and remedied.

Keeping Well

"The growth of science and the applications of science to practical affairs have no doubt brought, along with their advantages, serious difficulties. There is no ancient wisdom to guide us in the new circumstances. Keeping well has come to be increasingly dependent upon individual and social activities that receive their direction from science: the new conditions have to be studied intensively and systematically by the very methods that have brought them to be. We cannot return to nature. The remedy for the difficulties created by science is to be found in more science.

"The changes brought about by the industrial revolution have another bearing upon health that is becoming ever more obvious. Heretofore ill health or suffering was almost entirely the concern of the individual in distress and of his immediate relatives and friends. As time goes on the illness of individuals comes to be a matter of far-reaching social significance, in the political and economic phases. We know, of course, that a sick individual may become a menace to the health of his neighbors as a source or as a means of infection. Aside from this, how-

ever, the increasing complexity of our lives sooner or later makes the individual whose health is not up to standard a burden to others.

"In his industrial relations, the sick or ailing person is unable to carry his share of the total burden of work. He demands more than his share of overhead costs and of supervision. He often slows down the production of others, or adds to the hazards of their work. His incapacities eventually call for retirement and support at an unduly early age. Just as it is of advantage for every individual in the community that his fellow citizens be as intelligent, and well informed, and competent as possible, it is of advantage to every one of us to have everybody as well as possible: a large part of the waste and cost of illness falls upon the community, directly or indirectly. Those who are not themselves decidedly below normal must recognize that they are being unavoidably taxed by the hygienic shortcomings of others."—From a report on "A Museum of Health," by Benjamin C. Gruenberg, Ph.D., for the Committee on American Museum of Hygiene of the American Public Health Association.

A Study of a Type I Pneumococcus Epidemic at the State Hospital at Worcester, Mass.*

W. G. SMILLIE, M.D., F.A.P.H.A., G. H. WARNOCK, M.D.,
AND HAROLD J. WHITE

Director, Division of Public Health, Cornell University, New York, N. Y.; Junior Epidemiologist, State Department of Health, Albany, N. Y.; and Bacteriologist, Harvard School of Public Health, Boston, Mass.

AN epidemic of 110 cases of lobar pneumonia, which occurred at the State Hospital in Worcester, Mass., during the early months of 1937, offered an unusual opportunity to study the epidemiology of Type I pneumococcus infections.

We shall first present, in brief, the organization of the hospital. We shall then describe the epidemic as it swept through the institution, and indicate the various steps that were taken to check its spread.

DESCRIPTION OF THE HOSPITAL

The State Hospital for mental diseases at Worcester, Mass., has a fairly constant adult population of about 2,400 patients and 600 employees. It is well organized and expertly administered. It consists of two parts: the Main Hospital with some 1,800 patients and 500 employees, and the Summer Street Division with 600 patients and 100 employees. Summer Street Division is essentially an overflow hospital, to

which patients are transferred when approaching their period for discharge. It is 3 miles from the Main Hospital, and has its own separate staff, which has little contact with the Main Hospital staff. It receives no new patents, but admits only those patients that are transferred from the Main Hospital.

The institution has approximately equal numbers of male and female patients. The male and female patients are segregated in separate wards, and are classified in accordance with their mental condition. Each side of the Main Hospital has an infirmary, one for males, one for females, for the treatment of acutely ill patients. All patients who develop pneumonia or other acute illness on the general wards, and also in Summer Street Division, are transferred immediately to the infirmary for special medical or surgical treatment. All responsibility for the medical and surgical care of the acutely ill patients is centered in one staff physician.†

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

† We wish to express our appreciation of the fine cooperation and aid that was given to us by all members of the hospital staff, and particularly by Dr. F. H. Sleeper, Assistant Superintendent of the Hospital, and by Dr. W. E. Glass, staff physician in charge of acutely ill patients.

CHART I

Chart I shows the relationship of the epidemic of Type I lobar pneumonia at the Worcester State Hospital to the epidemic of influenza. Type I pneumococcus infection prevailed from the very first of January, and increased as influenza increased. The influenza outbreak was over by the middle of February, but Type I pneumonia did not decline until Type I pneumococcus antigen was given on March 2.

Bronchopneumonia has been quite prevalent among the patients of the hospital, as is always the case in institutions for mental diseases. Lobar pneumonia, however, has shown only a slightly higher incidence among the patients and staff of the hospital than in the population of the state at large.

The average annual incidence of pneumonia in the hospital during the past 4 years, including terminal bronchopneumonia, has been as follows: bronchopneumonia, 70.5 cases, 48 deaths; lobar pneumonia, 18.0 cases, 8 deaths.

Pneumonia of both types has been more prevalent in the male than in

the female patients of the hospital. The sex ratio of pneumonia incidence in these patients has been about the same as that of the general population.

	Males	Females
Proportion of Cases of Bronchopneumonia in the Institution	55%	45%
Proportion of Cases of Lobar Pneumonia in the Institution	64%	36%

As a general rule, bronchopneumonia has prevailed throughout the year, but lobar pneumonia has been much more prevalent during the late winter and early spring months than in the summer and fall.

THE INFLUENZA EPIDEMIC

Beginning early in January, 1937, an epidemic of moderately severe upper respiratory infection invaded the Main Hospital. This outbreak was similar in all respects to an epidemic of acute respiratory infection that prevailed at the same time along the whole North Atlantic Coast. Though many of the cases of this illness, both in and outside the hospital, were relatively mild, nevertheless it seems quite probable that the outbreak was true epidemic influenza.* The course of this influenza outbreak in the Main Hospital is indicated on Chart I.

Summer Street Division, although only 3 miles from the Main Hospital, escaped the influenza outbreak.

The hospital routine was completely upset by the epidemic. It was necessary to set aside certain special isolation wards for care of the acutely sick. The disease spread with rapidity throughout the institution. The peak was reached in the week of January 10, during which 96 cases occurred.

The hospital physicians noted that an unusual number of cases of pneumonia accompanied the influenza outbreak, but at first this fact caused no special concern.

The epidemic of influenza in the Main Hospital followed a characteristic incidence curve, and at the end of 6 weeks, conditions in the hospital had returned almost to normal. However, it soon became apparent that pneumonia was continuing long after the influenza epidemic had terminated. Instead of a concomitant decline in pneumonia with the decline in the incidence of influenza, as had been anticipated, lobar pneumonia continued unabated (see Chart I).

The hospital authorities noted that most of these cases of pneumonia were due to the Type I pneumococcus. They noted also that the onset of the attacks of pneumonia in those cases that occurred in the latter part of February was sudden, without a history of recent acute upper respiratory infection.

THE PNEUMONIA EPIDEMIC

On February 25, we were invited, in our capacity as State Consulting Epidemiologist, to aid in an investigation of the pneumonia situation at the Main Hospital.

A rapid survey revealed the following facts:

1. The epidemic of acute upper respiratory infection (influenza) at the Main Hospital, which began the week of January 3, had terminated, with no invasion of Summer Street Division.

2. Cases of lobar pneumonia were developing at a rapid rate in the Main Hospital. The infirmary was full of them, and new cases were coming in every day.

3. The cases of pneumonia were coming from many different parts of the hospital. The outbreak was not limited to one ward, to one occupational section such as farm hands and outdoor workers, or any single type of patient. Physicians, nurses, and attendants were affected as well as patients.

4. Practically every case of lobar pneumonia was due to the Type I pneumococcus.

5. The pneumonia outbreak was limited to the Main Hospital, and had not invaded the Summer Street Division.

6. There was no unusual prevalence of Type I pneumococcus pneumonia in the city of Worcester, nor in the State of Massachusetts as a whole.

In view of our previous experience with the Type II pneumonia epidemic at Bedford Hospital,¹ we felt quite certain that these findings indicated very strongly that the Type I pneumococcus had become widely distributed and had established itself in all parts of the institution. The source of the infection of the patients was not a single heavily infected individual

* The virus of epidemic influenza was obtained many times in our own and other laboratories by ferret inoculation of material obtained from victims of this epidemic.

(case or carrier) who transmitted the disease through a common vehicle such as food. Carriers must have become highly prevalent throughout the Main Hospital, and these disseminated Type I pneumococci among their fellow patients and the attendants.

A random sample of Type I carrier prevalence in the Main Hospital was made at once. We employed the same technic in detection of carriers that we have used in previous studies.² Our surmise was verified almost immediately. The survey indicated that at least 10 per cent of the patients of the Main Hospital harbored the Type I pneumococcus in the nasopharynx. This is a great contrast with a normal population, where Type I pneumococcus is found in the nasopharynx only once³ or twice in 500 cultures.

The hospital authorities were faced with a serious emergency. They were responsible for a large population of presumably highly susceptible persons who were continuously exposed to a virulent pneumococcus; for it was certain that Type I pneumococcus was widely dispersed throughout the hospital. The month of highest pneumonia prevalence in New England was at hand. New cases of Type I lobar pneumonia were developing every day. The rapid detection and isolation of all the Type I pneumococcus carriers in the Main Hospital was an impossible task, for there were 200 of them at least.

In the face of this situation we determined to make an attempt to check further spread of the epidemic of pneumonia by a rapid immunization of the hospital population.

The antigen* used was a preparation of an antigenically active polysaccharide of the pneumococcus, a compound similar to that described originally by

Schiemann and Casper⁴ in 1927 and more recently by Avery and Goebel⁵ under the name of acetyl polysaccharide. However, the sample had properties more nearly like the polysaccharide studied by Felton⁶ in that it was practically devoid of acetyl groups and yet was fully antigenic. The analysis of this antigen, made by Felton, was as follows:

Nitrogen—per cent	3.16%
Glucose number	25.1 %
Acetyl	1.0 %
Precipitin titer	1:2,500,000
Type I immunity in mice	1:50,000,000

In addition, Felton⁷ had tested the antigen on human beings and found that a single injection of 2 mg. stimulated antibody production effectively. The obvious advantages of an antigen of this kind are: it is soluble, stable, readily rendered sterile, and easily standardized to insure a satisfactory antigenic dose. We selected the Felton antigen for the above reasons, and also because of the fact that the antigen was immediately available.

The antigen was given subcutaneously in a single dose of 0.5 c.c. (2 mg.) to each adult. Over 1900 patients and attendants in the Main Hospital were injected on March 2, 3, and 4. No ill effects were produced.

The epidemic of pneumonia in the Main Hospital stopped almost immediately following the administration of the antigen. We cannot affirm, of course, that the antigen stopped the outbreak. It is possible that the epidemic might have stopped spontaneously on March 4. The results would have been much more clear-cut if it had been feasible for us to immunize every alternate person, but this was not possible. The hospital authorities felt that if we had any reason to believe that the antigen would give some protection, then we were unjustified in withholding this possible protection from a single patient. A small num-

* This antigen was kindly furnished to us by Dr. Malcolm of the Lederle Laboratories.

ber—about 200—of the patients and a few attendants refused the antigen, and this group served, in some degree, as a control series.

The course of the epidemic is shown graphically in Chart 2. The striking feature is that the pneumonia ceased abruptly following the administration of the antigen. Eighty-four cases of lobar pneumonia had occurred in the Main Hospital between January 3 and March 3. Nine cases of lobar pneumonia occurred after the antigen was given (from March 4 to June 1), only 4 of which were due to the Type I pneumococcus. Three of these had not received the antigen. One patient,

I. L., female, 78 years old, who had been given the antigen on March 31 developed lobar pneumonia on April 18 and died in 4 days. This case represents a definite failure of the antigen to protect against Type I pneumococcus invasion. Four of the other patients who developed lobar pneumonia (March 4 to June 1) had been given the antigen, but their pneumonias were due to some other organisms than the Type I pneumococcus.

Nine individuals were discovered who had a respiratory tract infection in which Type I pneumococcus was the prevailing organism, yet they never developed typical lobar pneumonia.

CHART 2

Graph of the Course of the Epidemic of Type I Lobar Pneumonia at Worcester State Hospital.

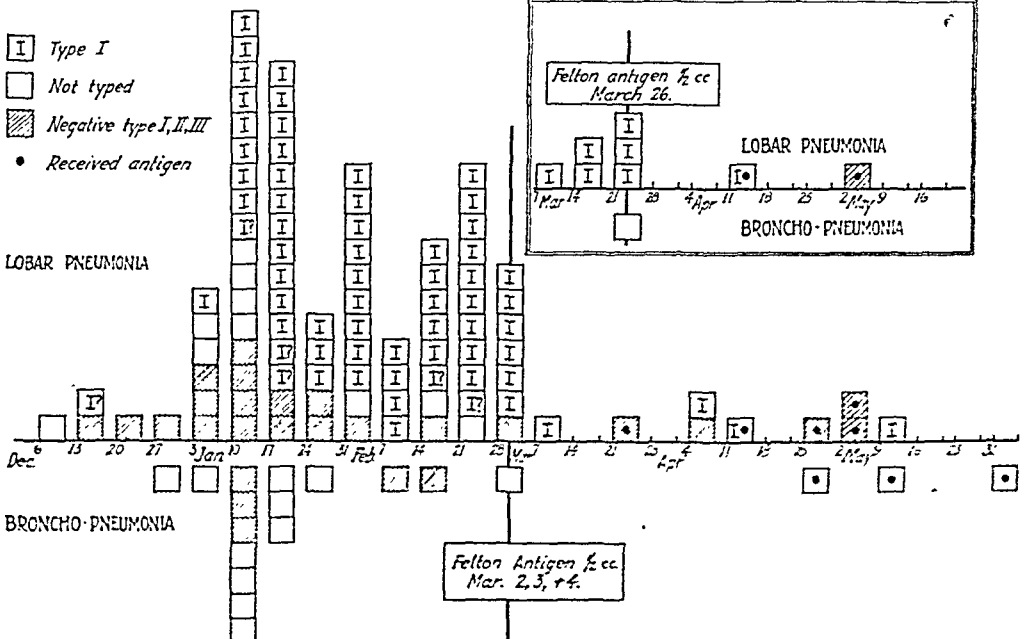

Each square represents a case of pneumonia. Bronchopneumonia cases are shown below the base line—lobar pneumonia above. Each case of proven Type I pneumonia is indicated by a [I] in the square. If the individual had received antigen, it is indicated by a dot within the square.

The small diagram inserted in the upper right hand corner represents the Summer Street Division outbreak which occurred after the Main Hospital epidemic had stopped.

WORCESTER STATE HOSPITAL

Admissions to Medical service, Main Hospital

Admissions to Medical service, Summer St Annex.

Three of this group were diagnosed clinically as cases of influenza, and 5 as common colds. One had an otitis media, followed by a fatal attack of Type I pneumococcus meningitis.

Case P. D.—Only one in this latter group (P. D.) had been given the antigen on March 3. He came to the infirmary on the evening of March 6 with a temperature of 104° F., pulse 120, and respirations 20 per minute. His leucocyte count was 16,000 per c.mm. and he gave every evidence of a beginning lobar pneumonia. The X-ray report next morning read "questionable early lobar pneumonia." His temperature fell by crisis on March 8. He was quite well on March 9. His sputum on March 7 was positive for Type I pneumococcus. He may be said to have run a complete course of pneumonia in 4 days.

It seems possible that the antigen which was administered 3 days previous to the onset of his illness may have given this patient some degree of protection against Type I pneumococcus invasion.

THE SUMMER STREET DIVISION PNEUMONIA OUTBREAK

The Summer Street Division, 3 miles from the Main Hospital, escaped the epidemic of influenza in January. At the time we began our investigation on February 28, no cases of Type I lobar pneumonia had occurred there.

The first case of Type I lobar pneumonia developed at Summer Street on March 9, nearly a week after the Main Hospital epidemic had ceased. This first patient was a newly appointed attendant, who had had no contacts with the patients of the Main Hospital. In view of these facts we should have been on the alert, and should have made an immediate investigation of Summer Street to determine the prevalence of Type I pneumococcus carriers there, and also to find the source of infection of this first case, but we did not do so.

Beginning on March 19, 5 cases of

Type I lobar pneumonia developed in quick succession among the male patients in the Summer Street Division. A fresh supply of antigen was obtained and all the patients and attendants were given a single subcutaneous injection of this antigen on March 26.

The outbreak of pneumonia at Summer Street Division ceased, following the administration of the antigen, just as it had done at the Main Hospital. The course of this outbreak is shown in the insert of Chart 2.

Cases—It will be noted that 2 cases of lobar pneumonia occurred in Summer Street, after the antigen was given. One of these represents a failure of the antigen to protect against Type I pneumococcus invasion. This individual, M. C., 63 years old, was given the antigen on March 26, developed Type I lobar pneumonia on April 17, and died in 4 days. The second pneumonia victim also had the antigen on March 26, but his pneumonia, which developed on May 2, was due to Type IV pneumococcus.

How can one explain the invasion of Summer Street Division by Type I pneumococcus after the epidemic in the Main Hospital had ceased? It seems most probable that the infection was introduced by carriers that were transferred to Summer Street from the infected zone.

Thirty persons had been transferred to Summer Street Division from the Main Hospital between January 1 and April 1. In Table I we have given the dates of transfer of these individuals.

Cultural studies of the nasopharynx of each of the entire group of transfer patients were made on March 29. Two, a woman transferred on March 1 and a man transferred on March 29, were found positive for Type I pneumococcus. The woman could not have been the direct source of the infection of the Summer Street cases of lobar pneumonia, because all the pneumonia cases had come from the male wards. The man was not responsible, because the infection had been introduced be-

TABLE I

Table of Transfer of Patients from the Main Hospital to the Summer Street Division from January 1 to April 1, 1937

February 1	3	1	
" 17	3	0	
" 19	4	0	One man, J. F., was convalescent from lobar pneumonia, which he had developed Jan. 14. Type I pneumococcus was never found in his sputum.
" 24	0	1	
March 1	0	2	One woman, L. W., was found to be Type I carrier on March 29.
" 3	1	0	
" 5	0	1	
" 8	2	0	
1st case of Type I pneumonia developed.			
March 25	4	0	
" 29	3	0	One man, M. D., was found to be a Type I carrier on March 29.

fore he arrived, probably between February 15 and March 1. (See Chart 2). It seems quite possible that patient J. F. (see Table I), who developed lobar pneumonia in the Main Hospital on January 14, and who was transferred to Summer Street on February 19, was the source of infection. We know that the new cases originated in the ward to which he was sent, and the outbreak began shortly after his arrival. The chain of evidence is not complete, however, since the throat culture of J. F. was negative on March 29, the date that the Summer Street carrier studies were first made.

We can be fairly certain that Type I pneumococcus was transferred from the Main Hospital to the male wards of Summer Street Division late in February. The infection spread through the male wards, but not the female wards. Subsequent events showed that both carriers and cases of Type I pneumococcus infection were produced following the introduction of the specific organism.

STUDIES OF TYPE I PNEUMOCOCCUS CARRIERS

When we began our study on February 27, the epidemiological evidence suggested that Type I pneumococcus carriers were widely distributed throughout the Main Hospital. Our first step was to take a random sample of cultures from the nasopharynges of patients and attendants from the various wards. We found almost at once that our surmise was correct.

The search for carriers was continued after the antigen had been given, and after the epidemic of pneumonia had ceased. A total of 280 different persons were tested in order to secure an estimate of the prevalence of Type I pneumococcus carriers in the hospital population. Twenty-two normal individuals were discovered to be harboring virulent Type I pneumococci—a carrier rate of 7.8 per cent—or 35 times the normal carrier rate of the general population. Sixteen of these normal carriers were found in the Main Hospital and 6 in Summer Street, most of them during the first month of the

study. The duration of the carrier state in each person is shown in Chart 3. It will be noted that most of the carriers cleared up spontaneously within a short time. By June 7 all but 5 had become negative.

Case—Only one discovered carrier later developed lobar pneumonia. L. R.—41 years old, male, Summer Street Division—was found to be a nasopharyngeal carrier on March 24. He was given 0.5 c.c. antigen on March 26. Some 650 other patients and attendants at Summer Street were inoculated on the same day. Twenty-four hours later he suddenly developed Type I lobar pneumonia.

It is possible that the antigen may have precipitated the attack of lobar pneumonia in this individual. However, 4 other patients at Summer Street were also known to be carriers, and were injected with antigen at the

same time as L. R., but without ill effect.

DISCUSSION

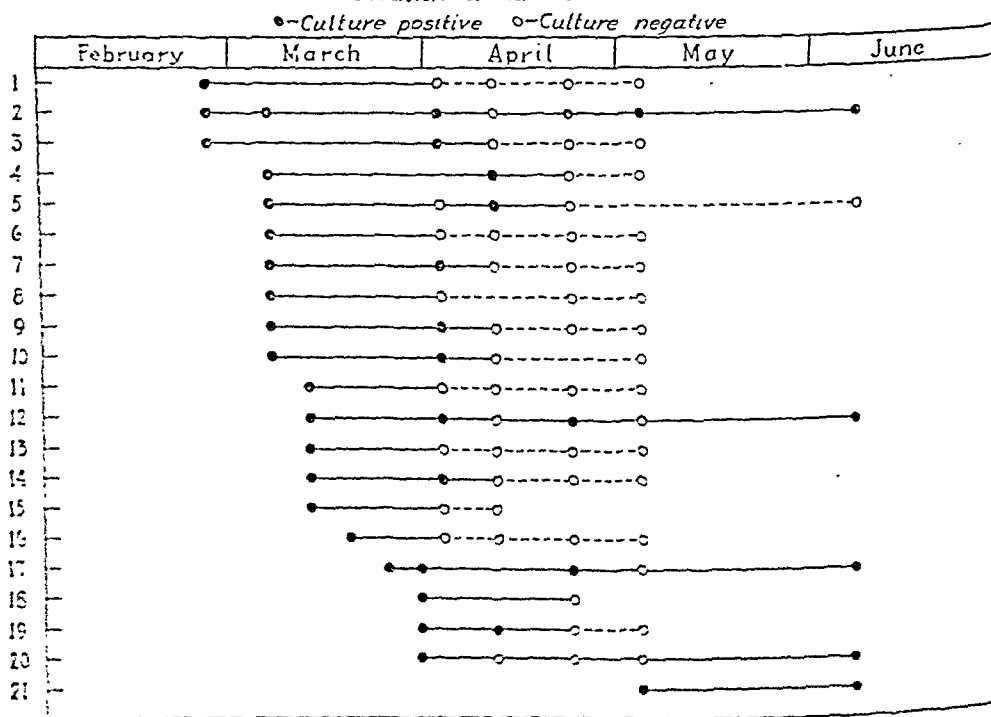

The epidemic of lobar pneumonia at the Worcester State Hospital was very extensive and serious in its effects. Between December and May, 110 cases of lobar pneumonia occurred, most of them in January and February.

The fatality rate of the epidemic was high, despite extensive use of Type I anti-pneumococcus serum. Many of the patients were debilitated and noncoöperative. The group in which no pneumococcus type was determined had a particularly high death rate (see Table II). These persons were extremely noncoöperative, and no sputum could be obtained from them. Often the type of infection was not determined

CHART III

The graph illustrates the duration of the carrier state in the 21 Type I pneumonia carriers that were discovered at Worcester State Hospital.

TYPE I PNEUMOCOCCUS CARRIERS Duration of Carrier State

because of the rapid progress and fatal outcome of the disease. It is probable that most of them were infected with Type I pneumococcus.

Sixty-seven pneumonia patients had a positive Type I pneumococcus sputum. It seems probable that most of the remaining 43 cases of the series of lobar pneumonia were also caused by Type I pneumococcus, but this point is difficult of proof. We made an attempt to do so.

TABLE II

Mortality Rates from Lobar Pneumonia in the Epidemic at the State Hospital in Worcester, Mass., 1937

<i>Lobar Pneumonia</i>	<i>Cases</i>	<i>Deaths</i>	<i>Mortality</i>
			<i>Rate</i>
Type I	73	16	22%
Not Type I, II or III	25	7	28%
Not typed	12	6	50%
Total	110	29	26%

When we began our study, many of the untyped patients were dead. We secured a list of all the convalescent pneumonia patients in whom Type I pneumococcus had not been found, and obtained blood from each of them. They were tested for the presence of Type I specific immune bodies, using standard methods.⁸ The bloods of 17 out of a group of 21 that were tested showed a protective power of 100 m.l.d. in standard mouse protection tests. The blood of 6 of these persons agglutinated the Type I pneumococcus in dilution of at least 1-5, and showed a mouse protection test of at least 1,000 m.l.d. We have felt justified in including these 6 persons in the list of those who undoubtedly had Type I pneumococcus pneumonia. They are indicated in Chart 2 as [I?]. We feel quite sure that all 17 convalescents that showed a blood protection power of 100 m.l.d., and many more of the group of lobar pneumonia patients as well, had also been infected

with the Type I pneumococcus, but we have no conclusive proof.

In addition to the actual cases of Type I lobar pneumonia, there were discovered 9 persons who were infected with Type I pneumococcus who never developed typical lobar pneumonia. We can make a fair estimate, therefore, that the total toll of the epidemic was at least 80 to 100 cases of Type I lobar pneumonia, together with at least 9 Type I pneumococcus infections that were not lobar pneumonia.

A cross-section of carrier prevalence indicated that there were at least 200 carriers of Type I pneumococcus in the institution during the epidemic; probably there were many more. As the pneumonia season ended, these carriers cleared up so that it is quite probable that by June 1, not more than 50 carriers remained. Most of these carriers would become negative before the summer was over.

The antigen was given in each hospital division at a time of high pneumonia prevalence. Practically all the carriers were given antigen, but there is no evidence that this procedure affected their carrier state. There is strongly suggestive evidence, however, that the administration of antigen at the Main Hospital checked the further spread of Type I lobar pneumonia in that institution. The disease then spread to Summer Street Division, after it had receded in the Main Hospital. The sudden abatement of lobar pneumonia at the Summer Street Division, following administration of the antigen was striking. The picture here was quite different from that at the Main Hospital. It might be claimed that the pneumonia epidemic at the Main Hospital had run its course when we began our study, and would have stopped on March 4 without any interference on our part.

The same argument cannot be em-

ployed at Summer Street. Conditions were ideal there for the spread of the infection. There were 600 patients and 100 employees. Presumably these persons were as susceptible to pneumonia as had been the group at the Main Hospital. The virulent infection had been introduced recently from the Main Hospital, and carriers became widely established. The cases began to develop rapidly in March, and stopped abruptly following universal administration of antigen.

If a single injection of 0.5 c.c. Type I pneumococcus antigen will protect susceptible individuals from an attack of Type I lobar pneumonia in the face of a heavy exposure and under conditions that are highly favorable for the spread of this infection, then this is a matter of far-reaching significance and worthy of continued study.

CONCLUSIONS

1. An extensive epidemic of lobar pneumonia in 1937 at the State Hospital in Worcester, Mass., which began during an influenza outbreak, was due to the Type I pneumococcus.

2. Type I pneumococcus carriers became widely distributed throughout the Main Hospital. These carriers, and not the actual cases of pneumonia, were responsible for the spread of the infection.

3. The epidemic at the Main Hospital ceased abruptly following administration of Type I soluble antigenic substance (Felton antigen) to the hospital population.

4. A fresh outbreak of Type I lobar pneumonia occurred at Summer Street Division (a branch hospital) 1 week after the epidemic at the Main Hospital abated. This infection entered Summer Street Division through normal carriers of Type I pneumococcus, who were transferred from the Main Hospital to the subsidiary hospital. The administration of antigen at Summer Street was also followed by immediate cessation of this outbreak.

Contact

MY last word is this. Every person who contacts the public in any health organization, no matter what it may be, has some effect on public relations. If you have somebody at the telephone desk, or somebody in the reception bureau, whose attitude is gruff or sharp, he can do more harm than the head of the organization can undo. When we turn the public away with an uncivil answer, we create bad

public relations. There really ought to be a training course, however brief, in every organization employing a large personnel in the public health field, to teach their staff how to meet the public, what to say to them, and how to say it. Those who can't learn the knack should be placed where they do not deal with their clientele.—*The Health Officer*, January, 1938, page 435.

The Health Department in the Field of Medicine*

R. H. RILEY, M.D., DR.P.H., F.A.P.H.A.

Director, Maryland State Department of Health, Baltimore, Md.

FOR the purpose of this discussion, "the field of medicine" is here defined to include all activities of the scientific staff of the health department who are primarily concerned with the diagnosis, treatment, and prevention of remediable physical conditions.

In considering how dependent curative medicine is on preventive medicine, it is very difficult to determine where one ends and the other begins. It is doubtful if any phase of curative medicine is complete without due regard to prevention, even though it may be only the immunization of contacts against a communicable disease or the necessary advice to ward off complications or sequelae of acute infectious diseases.

There has been a remarkable expansion of public social services during recent years. These developments reflect the growing sense of responsibility of the community for the health and well-being of the individual members of it. The ordinary citizen today is not only to have a better chance of coming into the world in good health, but must be given every opportunity of making the best of his life before he leaves it.

The fruits of this philosophy are seen in the maternity and child welfare

services, educational reforms, preventive and curative health services, slum clearances and in programs for improved housing.

Highly organized federal, state, and local health departments exist which are responsible for the control of communicable diseases and for sanitation. The medical profession works no longer as independent individuals in the field of public health, but perforce as team mates with health departments and through such teamwork results may be accomplished which could not be obtained by individual action.

The medical activities of the Maryland State Department of Health are considered below under headings arbitrarily chosen to follow the activities of the several bureaus and divisions of the department.

Field of Communicable Diseases—In Maryland there is a full-time trained medical officer of health in each county. All services rendered from the central office are conducted through the county health units and include diagnostic aid, epidemiological investigations, preventive inoculation programs, laboratory services, and assistance required to protect water, milk and food supplies.

With regard to the control of certain diseases such as tuberculosis, syphilis, gonorrhea, and poliomyelitis, the health department provides not

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

only diagnostic and therapeutic services, but assists in hospitalization. The responsibility for hospitalization and other special types of cure is not predominantly under the health department.

(a) *Tuberculosis*—In addition to the general diagnostic activities provided by the health department, mainly in the forms of tuberculosis clinics, the state also makes provision for the hospitalization of cases in the 4 state tuberculosis hospitals. Three of the local health officers conduct clinics; the other clinics are conducted by staff members of the State Tuberculosis Sanatoria. Provision is also made for the epidemiological investigation of all reported cases, follow-up services with bedside nursing care in some instances, the tuberculin testing of selected groups of individuals, and for X-ray examinations, free of charge, for all cases recommended by the clinician or health officer conducting the tuberculosis clinic or having charge of individual cases of tuberculosis. Portable X-ray machines are now provided by the state which make it possible to have such examinations at even the most isolated clinics.

In our tuberculosis work in Maryland, to maintain the cordial coöperation of the family physician, the clinician conducting the tuberculosis clinics refers all reports and recommendations directly to the family physician and not to the patient. The physician depends largely on the Health Department to facilitate early hospitalization of tuberculosis patients and coöperates fully in the epidemiological investigation of cases and is of great service in instructing the families in preventive measures.

(b) *Syphilis*—The Maryland State Department of Health conducts a diagnostic service through its laboratories which perform serologic tests for syphilis, without charge. The Balti-

more City Health Department Laboratory also extends this same service to the physicians practising in Baltimore City. At the syphilis clinics, blood specimens are taken from all patients attending, and the health officer also takes blood specimens from private patients who may be referred by private physicians. Darkfield examinations are made at some of the clinics and in the central laboratory when specimens are forwarded either by the health officer or private physicians. Reports are sent directly to the physician in charge of the case and in no instances are reports sent direct to patients. These diagnostic aids are available for all types of syphilis and gonorrhea, and physicians use the service freely.

We are having a favorable response to our request to the hospitals to make the Wassermann test a routine diagnostic procedure for all admissions. We feel that if this request falls short of its complete goal, if we obtain the test on all maternity cases, we will have made considerable advance. In all of our prenatal clinics held throughout the state, the Wassermann test is a routine procedure and all patients giving a positive reaction are urged to take treatment either from their private physicians or at a clinic.

In our present program in Maryland we have 50 clinics, 40 in the counties, and 10 in Baltimore City, conducted by local health officers in some instances or by selected clinicians who are paid for their services by the state and city. The Department of Health provides neoarsphenamine and preparations of bismuth or mercury for treatment in accordance with modern therapeutic methods. These drugs are supplied without distinction as to the patient's ability to pay the physician a full fee or any fee for the service. This method makes it possible for private physicians to provide medical care to

many patients who cannot afford to pay for medical services.

The services of the county health officers and public health nurses are available to follow up lax cases of the private physician when requested to do so. This is an important feature since only by sufficiently sustained treatment can syphilis be rendered non-infectious and in a number of cases clinical cure procured. A few physicians in their regular practice are doing excellent case finding work with their patients. In an epidemiological investigation the important question is, "From whom did the patient acquire the disease and to whom may he or she have transmitted it?" Early syphilis, syphilis in pregnancy, and congenital syphilis offer the best field for epidemiological investigation. In Maryland a complete case history is obtained from all patients attending the clinic, and the local health officer and his staff of nurses begin their epidemiological investigation from that point.

The State Department of Health furnishes consultation service which has made it possible for local health officers, clinicians, and private physicians to have the benefit of expert advice on the diagnosis of syphilis, especially its late manifestations, and to have outlined for them an approved method of treatment.

We have been able, with the assistance of the consultant on venereal disease, to direct particular attention to the early detection and treatment of neurosyphilis and cardiovascular syphilis, the two types which cause the greatest economic loss from incapacity and early death. In all cases giving a positive Wassermann reaction, treatment is given for 9 months before spinal fluid tests are done. By this procedure we find potential cases of general paralysis of the insane and prevent their becoming a total liability in so far as the state is concerned.

The Baltimore City Health Department has a Bureau of Venereal Disease under the supervision of a full-time director. The city conducts clinics and maintains close contact with out-patient departments conducted by the several hospitals in Baltimore City. A complete follow-up service is provided and all activities are conducted in close coöperation with the practising physicians of Baltimore City.

Our general plan of treatment of all syphilitic cases conforms to the standard plan as submitted by Dr. Parran's committee. We are also meeting no small degree of success in the treatment of syphilis in infants, and in Baltimore City there are several clinics just for congenital cases.

(c) *Pneumonia*—A number of health departments have recently embarked upon an extensive pneumonia control program which includes not only greatly extended diagnostic facilities, but in some states the manufacture and distribution of therapeutic sera for the more common types: *viz.*, type I and type II.

In Maryland, laboratory diagnostic assistance has been extended to all physicians and the demand for this service has steadily increased. On the request of the attending physician, the sera available for the treatment of the disease are furnished at cost.

(d) *Preventive Inoculations*—Diphtheria toxoid administration in Maryland is carried out almost entirely by the local health officer and his staff. Pre-Schick testing is not a routine procedure in the state program, but in several counties where special studies have been conducted, the Schick test has been made previous to inoculations with toxoid.

Post-Schicks are done on the great majority of persons who have received diphtheria toxoid. It has been estimated that 75 or 80 per cent of the school children have received diphtheria

toxoid, and the percentage of preschool children receiving diphtheria toxoid has increased each year. Health departments have a definitely fixed legal responsibility in the control of communicable diseases of which preventive inoculations is only one. I believe that when the family physician recognizes his responsibility to inoculate all children under 1 year of age in his clientele, the work of the health department in this field will gradually become less and less.

In several of the counties the toxoid administration has been carried out largely by the practising physicians, the State Department of Health supplying the toxoid in return for which the physician furnishes the local health department with certain statistics pertaining to the number of injections given. Diphtheria antitoxin is furnished free to physicians for use for private as well as for indigent patients.

Antirabic treatment is furnished free of charge to all patients and is given to those living in Baltimore by a physician on the staff of the State Health Department. Indigent patients living in the counties receive treatment at the local health department.

(e) *Services for Crippled Children*—The care of physically handicapped children includes: case finding of poliomyelitis reported by private physicians and health officers, and of other physically handicapped children referred by the school board through its school survey for crippled children, local health officers, social welfare workers, and private physicians; the organization and supervision of clinics conducted by orthopedic surgeons paid on a per diem basis by the State Department of Health.

The orthopedic surgeons examine patients, make recommendation for hospitalization, surgical care in hospitals, and give definite instruction to the physiotherapists for after-care in the

home, and reëducation of affected muscles.

In coöperation with the Board of Education handicapped children are provided for in special classes, and with home and bedside teaching, and rehabilitation. The orthopedic surgeon is in full charge of all patients attending his clinic from date of examination to final discharge of the patient.

(f) *Laboratories and Research*—In addition to the laboratory diagnostic activities, the central laboratory of the Maryland State Department of Health and, to a more limited extent, the branch laboratories conduct medical and technical research in fields which are intimately related to the practice of medicine, with particular emphasis on immunology and serology. Professional members of the staff of the laboratories are available for special assignments to assist county health officers in field investigations and consultations with physicians with regard to the diagnosis and prevention of communicable diseases and the protection of public water supplies. In Baltimore, the City Health Department conducts similar laboratory services, and in addition has an active research program at Sydenham Hospital.

(g) *Maternity, Infancy and Child Hygiene*—The field of maternal and infant hygiene includes to an increasing degree the provision of consultant and technical services. The state has for a number of years conducted itinerant maternal and child health services designed to assist local health officers and private physicians in the maintenance of a high standard of maternal and infant care.

A nurse instructor with special knowledge of maternal and child hygiene has been assigned to some of the counties to devote most of her time instructing nurses and midwives in the technic of this phase of work. Three nurses with obstetrical training and experience have

been employed for this service. The obstetrical nurses deliver selected indigent cases and supervise the work of the midwife. The service has been made available upon the request of the physician for assistance at the delivery in patients unable to provide nursing service for themselves. This service has been most favorably received by the local practitioners.

(h) *School Examinations* — Here again the sympathy and support of the general practitioner is most important if it can be obtained. In a number of communities, where the private practitioner, at the request of the county health officer, has conducted the school examinations they have found this to be a more satisfactory arrangement. The examinations include physical examination of the chest, nose and throat, sight, and hearing. Correction of defects found at school examinations is made at one of the local hospitals, and the physician's fee and hospital charges are met by the local community. In school examinations it is impossible to avoid entering into "the field of medicine" for conditions such as scabies, impetigo, ringworm, and pediculosis. In the rural sections these conditions, if not treated by the members of the health departments will go untreated, as the majority occur among groups unable to afford the services of a physician and in many instances unable to purchase the necessary drugs. In Baltimore City in school work, the policy has long been to allow the family physician, if there is one, to have the last word.

Control of communicable diseases in the schools is a health department activity of major importance, and frequent inspections are made by the health officers in connection with other measures in carrying out this function.

(i) *Dental Clinics*—I do not know of any better organized piece of real health work than the dental clinics.

They are held in some localities where no dental facilities are available. Dentists are employed on a part-time basis in some localities and on a full-time basis in others. The clinics are free to those unable to pay, but some are on a self supporting basis, fees being raised by Parent-Teacher Associations and clubs to pay part of the dentists' salaries.

(j) *Field of Public Health Nursing* —We conduct a generalized public health nursing program in which primary emphasis is placed on public health educational and promotional activities. The nurses' activities also include services in the schools and certain specialized services including case finding, assistance and follow-up in connection with the operation of syphilis control clinics, prenatal, tuberculosis, and mental hygiene clinics, and other such functions which have a medical or therapeutic aspect as contrasted with the more restricted preventive measures.

(k) *Disaster Relief* —Disasters of almost any nature, either fire, flood, or earthquake, are invariably followed by problems which are entirely medical in nature aside from the physical accidental injuries. In communities where well organized health departments exist, the health department has been the center of activities and has generally been designated as headquarters for not only official organizations participating in relief, but for other national and local organizations who have always availed themselves of the opportunity to be associated with the health department in its relief program. In major disasters the health officer should inform the public as well as the physician where he may be reached by telephone and the location of the central and local distributing points.

(l) *Control of Typhoid Carriers* —In the field of preventive measures, the control of chronic typhoid carriers

presents a difficult problem. In some states, medical, surgical, nursing and institutional care may be provided by the state department of health at the expense of the state. We have been successful in a number of instances in inducing chronic typhoid carriers to undergo operations for the removal of the gall-bladder with a view to possible removal of carrier restrictions. This is usually not urged, especially for the older carriers. In the limited number of cases thus far so treated, the results have been most satisfactory and the surgeons have become keenly interested in this phase of work.

RELATIONS WITH THE STATE MEDICAL SOCIETY

All programs pertaining to the practice of medicine, either curative or preventive, are discussed with the Council of the Medical and Chirurgical Faculty—the State Medical Society—which acts as a Committee on Public Health, and through this committee the voice of the private practitioner is heard and his interest and coöperation are thus maintained.

We have not attempted any program in "the field of medicine" without first a full and frank discussion of the subject with the State and County Medical Societies. We have been fortunate in having our plans endorsed by the profession, and the Medical and Chirurgical Faculty has addressed letters to the physicians of the state calling their attention to subjects deserving their wholehearted attention in curative medicine as well as in preventive.

The coöperative support of physicians in Baltimore was shown when the

Baltimore City Medical Society on the recommendation of its own Committee on Public Health and Relations resolved,

... that the best interest of the community would be better subserved by the Baltimore City Medical Society requesting the City Health Department to put on a campaign on diphtheria immunization and that the physicians of the city coöperate with the Health Department to that end.

The physicians in Maryland have given freely of their time in assisting at clinics, conducting examinations, and administering biologics used as preventive measures, and we are constantly reminding the profession that such work as the eradication of diphtheria, the reduction of syphilis, and the adequate care of expectant mothers and young children must rest largely in the hands of the practising physician.

The cordial relations which exist between the state, city, and county health departments and the medical profession has eliminated many of the defects of earlier days. We believe that the results accomplished justify the means and at present, at least, there is no need to defend the efforts of the Maryland State Department of Health in "the field of medicine."

In the midst of our manifold perplexities, the progress we have made should hold encouragement for the future. We can say with Carlyle,

Doubtless this age is also advancing. Its very unrest, its ceaseless activity, its discontent contains matter of promise. Knowledge, education are opening the eyes of the humblest; are increasing the number of thinking minds without limit. This is as it should be; for not in turning back, not in resisting, but only in resolutely struggling forward, does our life consist.

The Dark Adaptation Test for Vitamin A Deficiency*

CARROLL E. PALMER, M.D., F.A.P.H.A. .

*Passed Assistant Surgeon, U. S. Public Health Service,
Washington, D. C.*

THE dark adaptation test for vitamin A deficiency is based on a common and familiar experience which consists essentially of the observation that in order to "see" in relative darkness the human eye must become accustomed or "adapted" to darkness. The physiological characteristics of this phenomenon, known as dark adaptation, have been extensively studied. Fundamentally the process is a photochemical reaction in which visual purple, the light sensitive pigment in the rods of the retina, is desensitized to dim light by exposure to bright light and is resensitized to dim light through regeneration in darkness.

It is a well established fact that moderately severe vitamin A deficiency is accompanied by an abnormality of the dark adaptation reaction, known as functional night blindness, which is manifested by an inability to see at night or in a dim light. Also, a direct chemical relation between vitamin A and visual purple has been proved. The precise physiological relation between vitamin A, visual purple, and rod function is not yet known; but it has been postulated that the amount of vitamin A in the body may

influence dark adaptation. Furthermore, although no satisfactory proof of a functional relationship between vitamin A and dark adaptation has been furnished, it seems not unlikely that mild degrees of vitamin A deficiency might be expected to result in delayed adaptation.

On the basis of these considerations a number of workers, particularly during the past few years, have investigated the measurement of vitamin A status by means of dark adaptation tests.

Using the Birch-Hirschfeld photometer, Jeans and Zentmire^{1,2} devised a test and applied it in a survey of Iowa school children. As a result of the study these investigators drew the striking conclusion that between 26 and 79 per cent of 404 children examined showed evidence of vitamin A deficiency. I. O. Park^{3,4,5} reported the test to be satisfactory for studies of adults and children and confirmed the impression of the comparative prevalence of vitamin A deficiency. Jeghers^{6,7} also used the test on adults and found mild to moderate degrees of vitamin A deficiency to be common among many supposedly healthy adults. However, Snelling⁸ concluded that the Birch-Hirschfeld photometer was unsatisfactory, both in adults and in

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

children, for measuring small differences in dark adaptation such as might accompany vitamin A deficiency.

A later paper by Jeans, Blanchard, and Zentmire⁹ included a description of a new instrument, the biophotometer, and an improved standardized technic for measuring dark adaptation. Reviewing their earlier survey findings in the light of results secured with the new method, these workers essentially confirmed their previous conclusions regarding the prevalence of vitamin A deficiency in children.*

In a very recent report, Palmer and Blumberg¹⁰ presented data, secured by the U. S. Public Health Service and based on a study of the biophotometer technic as a method for detecting mild vitamin A deficiency in the routine survey of school children. The material included the results of biophotometer tests of 585 children in the 3rd to the 8th grade of elementary schools in Maryland and the District of Columbia. In this study it was observed, as mentioned by Jeans, Blanchard, and Zentmire, that considerable improvement in readings, apparently due to a learning factor, resulted from repeated testing of the same children. Also, a great variation was found in successive tests of the same individual. These findings were interpreted as indicating that very little dependence could be placed on results based on a single test of a child. In addition to indicating these disturbing aspects of the test, it was pointed out that considerable uncertainty exists regarding proposed methods for classifying biophotometer measurements as representing different levels of vitamin A nutritional status. As a result, the conclusion was reached that the bio-

photometer technic does not yet appear to constitute a reliable method for detecting mild degrees of vitamin A deficiency in the routine survey of school children.

FEEDING STUDY

Some further data bearing on the problem of dark adaptation tests and vitamin A are now available from a special study carried out in conjunction with the U. S. Public Health Service surveys in Maryland. The character of this study was dictated primarily by the fact that nearly all of the evidence presented in the literature for considering the dark adaptation test to be an index of vitamin A status is based on improvements in adaptation measurements following the ingestion of the vitamin. However, no adequately controlled experiments have been reported in which changes in the dark adaptation reaction have been studied for comparable groups of individuals, one group being given vitamin A and the other group not being given the vitamin. In view of this the following experiment was undertaken.

Method—From among a group of approximately 450 3rd to 8th grade school children who had been given a biophotometer test in February and March, 1937, 106 were selected for special study. This selection was made on the basis of the results of the biophotometer test, the largest proportion of the children being those whose dark adaptation test marked as "deficient" in vitamin A, according to the criteria of Jeans, Blanchard, and Zentmire, a smaller proportion, those marked as "borderline subnormal," and a few marked as "normal." No children were included who had any evidence of ocular pathology as revealed by ophthalmoscopic examination. The children were separated, by random shuffling of their initial record cards,

* Jeghers¹¹ recently reported the results of a biophotometer study of 166 medical students, 35 per cent of whom showed photometric evidence of vitamin A deficiency.

into two groups, one to serve as a feeding series and the other as a control series.

As a preliminary to the feeding study, each child was given 3 biophotometer tests in addition to the initial test in order to obtain supplementary data regarding the reliability of the readings. Following this for 5 weeks each child was given a biophotometer test at weekly intervals, during which the children in the feeding group each received an average daily supplement of 18,000 International Units of vitamin A (equivalent to more than 8 teaspoonfuls of U.S.P. cod liver oil), or a total of 630,000 International Units in 5 weeks, in the form of halibut liver oil capsules.* The control series received daily supplements of 0.05 International Units of the vitamin in similar capsules. Parental permission was obtained to give vitamin A supplement to all of the children. It is obvious that the children receiving the supplement of 0.05 units of vitamin A per day constitute the control group. As an assurance that the dietary supplement was actually consumed, the capsules were given to the children at the school and were swallowed under the direct observation of an attendant. It may be stated also that none of the children or parents, and none of the persons actually making the biophotometer tests knew which was the feeding and which was the control series.

Results—The biophotometer test, as described by Jeans, Blanchard and Zentmire,⁹ and as employed in this study, consists of a series of visual threshold measurements or readings which are made following a standardized exposure of the subject's eyes to a bright light. The interpretation of

the test is assumed to depend on the form and position of the dark adaptation curve derived from the threshold measurements. According to the test procedure which has been proposed, however, it is presumed possible to judge the status of vitamin A nutrition from the values of threshold measurements made at two points on the adaptation curve. The more significant of these measurements is considered by Jeans, Blanchard, and Zentmire⁹ to be the reading made at about 25 seconds (20–30 seconds) following exposure to the bright light*; of lesser significance these workers consider the reading made at 10 minutes after dark adaptation begins. In accordance with this practice, therefore, the presentation of results of the study is limited to the data in Table I and Figure I. In the table the means and standard deviations† are given for both groups of children for readings made at 25 seconds and at 10 minutes after dark adaptation begins. The results of the

* It may be mentioned that a reading taken after only 25 seconds of dark adaptation probably measures the action of the cones of the retina, rather than that of the rods. Much is known of the relation between vitamin A and rod function, but no relation has ever been shown between vitamin A and the retinal cones.

† The threshold measurements used in this analysis are expressed as logarithms of millifoot candles of light intensities. Most workers, however, have used the absolute values of millifoot candles, and the criteria proposed by Jeans, Blanchard, and Zentmire⁹ for judging vitamin A deficiency have been expressed in such terms. Sufficient and sound reason, however, dictate the use of the logarithmic scale: First, the scale with which the biophotometer is equipped, and in which the readings are recorded, is a logarithmic scale of millifoot candle values expressed in arbitrary units. Second, the threshold measurements obtained in the dark adaptation test constitute a type of sensory measurement for which logarithmic scales have been proved in the past to be most satisfactory. Third, the practical utility of the logarithmic scale becomes apparent when frequency distributions of biophotometer measurements are made. Such distributions are very markedly skewed on the absolute millifoot candle scale, while they follow very satisfactorily the normal probability distribution on the logarithmic scale. Through the use of the logarithmic scale, therefore, it is possible to make use of those theoretical considerations which have been found applicable to the normal frequency curve.

* The vitamin A potency of the preparation was confirmed by assay, through the courtesy of Dr. E. M. Nelson, Chief, Vitamin Division, Food and Drug Administration, U. S. Department of Agriculture.

TABLE I

Means and Standard Deviations (Logarithms, Millifoot Candles) of 25 Second and 10 Minute Biophotometer Readings for an Experimental Group of 54 Children Given Vitamin A Supplement and a Control Group of 52 Children; All Children Given 4 Preliminary Tests Followed by Weekly Tests for 5 Weeks

Time During Adaptation When Reading Was Taken	Group of Children Tested	Preliminary Tests				Subsequent Weekly Tests					
		1st	2nd	3rd	4th	1st	2nd	3rd	4th	5th	
		Mean, biophotometer measurements (logarithms, millifoot candles)									
25 seconds	Vitamin A	+0.088	+0.009	-0.030	-0.072	-0.149	-0.194	-0.193	-0.245	-0.284	
(20-30 seconds)	Control	+0.025	-0.029	-0.058	-0.080	-0.122	-0.151	-0.151	-0.203	-0.313	
10 minutes	Vitamin A	-1.448	-1.601	-1.623	-1.706	-1.822	-1.810	-1.832	-1.791	-1.950	
	Control	-1.459	-1.540	-1.544	-1.600	-1.719	-1.669	-1.726	-1.659	-1.885	
Standard deviation, biophotometer measurements (logarithms, millifoot candles)											
25 seconds	Vitamin A	0.204	0.147	0.199	0.175	0.195	0.177	0.184	0.175	0.215

10 minutes	Vitamin A	0.381	0.313	0.296	0.350	0.333	0.291	0.377	0.432	0.352	
	Control	0.367	0.312	0.317	0.367	0.340	0.350	0.400	0.436	0.430	

4 preliminary trial tests are given first, followed by the results of the weekly tests given after the supplementary feeding was begun. The data shown in the figure illustrate graphically the changes in the mean values of the threshold measurements for the successive tests. The ranges of the measurements are illustrated by lines representing two standard deviations above and below the mean values.

With regard to the general aspects of the results of the analysis, two striking facts may be noted: (1) it is evident that marked improvement in the averages of the threshold measurements occurs in successive tests in both the children fed the vitamin concentrates and in those not fed; (2) the measurements show a very high degree of variability as indicated by the ranges marked out by two standard deviations above and below the means.

Study of the data for the reading made at 25 seconds shows that the means of the first preliminary test for both the feeding and control groups fall into the range of values which are considered, by the criteria of Jeans and coworkers, to represent vitamin A deficiency. The average for the group that was subsequently given large doses

of vitamin A, the feeding group, is a little less than the average for the control group; on the fourth preliminary test, however, the averages for the two groups are almost identical. During the 5 weeks of supplementary vitamin feeding, the averages for both groups for the 25 second reading continue to increase, the averages of the feeding group being slightly higher except for the readings made at the end of the feeding period. None of the differences between the averages for these measurements is however, statistically significant. It may be mentioned, also, that at the end of the experiment 45 per cent of the children in the feeding group gave readings which are not considered normal by present criteria, and a slightly lower percentage of children in the control group gave similar readings.

The data given for the 10 minute adaptation reading are similar in general to those given for the 25 second reading. The averages for the initial preliminary test for both groups are essentially identical, and for this measurement the averages fall well within the range which by the proposed criteria is considered to represent normal vitamin A intake. On the fourth pre-

FIGURE I—Changes in means and standard deviations of biophotometer readings made at 25 seconds and at 10 minutes for feeding and control groups of children given 4 preliminary tests, followed by weekly tests for 5 weeks

liminary test the average for this reading for the group of children given large doses of the vitamin is somewhat higher than the average for the control group. The difference between the averages for the feeding and control groups is maintained at approximately the same value throughout the feeding period except for the measurement

made at the end of 5 weeks, at which time the averages for the two groups are again very similar. It is apparent that the measurement made 10 minutes after the beginning of the adaptation period shows great variation, and there seems to be some difference in favor of the feeding group. However, the major part of the difference appears

even before feeding was begun, and the averages of the two groups are essentially alike at the end of the feeding period. As a result of these findings, particularly in view of the enormous variability of the measurements, it is not possible to attribute the improvement in the measurements conclusively to the supplementary vitamin feeding.

DISCUSSION

In attempting to evaluate the meaning of this study, discussion of a number of points would appear indicated. These concern the possibility of fortuitous increase of the vitamin intake in the control group of children studied, the method of selecting the children for study on the basis of levels of deficiency determined by biophotometer tests, the insufficiency of evidence of the actual quantitative relationship between vitamin A and dark adaptation, and the relation of the herein presented findings to those of other workers in the field.

In connection with the first point, it is apparent that no rigorous control of the home dietaries was obtained for the children under study. Accordingly, it is possible that a coincidental increase of vitamin A in the diets of the children in the control group occurred. However, a significant change in the vitamin A content of the home diet in a large percentage of the 52 control subjects at this time—February, March and April—would appear to be unlikely.

With reference to the selection of subjects, it may be said that an attempt was made to select as many as possible of those children whose dark adaptation measurements indicated deficiency according to those criteria which have been proposed in the literature. However, in light of the shortcomings of the biophotometer technic, discussed in a previous publication,¹⁰

it is possible that the interpretation of deficiency may be inadequate, and as a result the possibility exists that few or no children with vitamin A deficiency were actually included in this study. These latter impressions are further supported by the findings of the present investigation that a large proportion (45 per cent) of the children who originally had subnormal or borderline readings failed to give normal adaptation measurements at 25 seconds even after receiving vitamin A concentrates. If such a large proportion of apparently healthy children fail to give "normal" measurements after supplementary feeding, it seems indicated that the proposed standards for the dark adaptation measurements with the biophotometer may be incorrect or too rigorous.

The question of the factual evidence now available for believing that a relationship exists between vitamin A and dark adaptation measurements is of importance in connection with the interpretation and evaluation of the results of this and other studies. In general, evidence for this belief is based on experiments in which dark adaptation measurements are made before and after a period of vitamin supplementation on groups of subjects without negative and comparable control studies. In the case of the feeding group studied here, a procedure was followed in which two groups, one fed and the other not fed the vitamin supplement, were tested. Since the results of this study, where a negative control group is included, are unsatisfactory and inconclusive, it is indicated that conclusions based on studies which do not include provision for controls may be considered questionable.

On the basis of the study here presented and the related discussion, it seems necessary to conclude that the biophotometer technic, in its present

form, cannot yet be considered reliable or satisfactory for detecting mild forms of vitamin A deficiency in children. It is apparent that this conclusion is not in harmony with the impressions of some other investigators. Reasons which form the basis of the differences in views regarding dark adaptation tests and vitamin A deficiency have been given in this and in a previous publication.¹⁰ These reasons appear cogent, but a careful evaluation of all the evidence now available concerning the biophotometer test reveals that conclusive results, either favorable or unfavorable, have not yet been obtained. On the basis of apparently sound theoretical considerations, it seems very probable that it *should* be possible to measure quantitatively the vitamin A nutritional status by means of dark adaptation tests. Equally sound considerations would appear to indicate that a satisfactory and practical methodology has not yet been developed for routine application in surveys of children.

SUMMARY

An investigation is reported in which the effect of vitamin A administration on biophotometer dark adaptation measurements in school children was studied. The results showed no significant difference in the improvement in biophotometer measurements between a group of children whose diet was sup-

plemented and a control group whose diet was not supplemented with vitamin A. The need is indicated for further work on the relationship between dark adaptation and vitamin A and on methods for measuring the relationship, particularly in surveys of children.

Present Status of Phosphatase Test for Pasteurization *

WALTER VON DOHLEN TIEDEMAN, M.C.E., F.A.P.H.A.
State Department of Health, Albany, N. Y.

HEALTH officials have long dreamed of the development and use of a practical test for pasteurization. Many tests have been tried and found wanting. In fact a test of this kind has long been a sort of mirage always alluringly just out of reach but never quite attainable.

In view of this it will not be surprising to encounter some skepticism, on the part of those who have not had experience in the use of the test, when we say that the millenium has come. A practical means of determining whether or not milk and cream have been properly pasteurized is now available in the so-called phosphatase test.

Examination of our own records of outbreaks of disease traced to raw milk have convinced us that pasteurization of milk is a practical and necessary safeguard to the public health. The opinion of health officials generally on this subject was well expressed by the following statement in a recent editorial on "Pasteurization in England and America" in the *American Journal of Public Health*: "Raw milk, whether in England or America, should no longer be permitted to impede public health progress." Health officials who recommend the use of pasteurized milk should be in a position to assure the

public that milk labeled "pasteurized" has actually received sufficient heat treatment to make it safe. The phosphatase test is the first means the health officer has had to determine whether a sample of milk has been adequately heat treated.

The literature has contained reports upon tests for heated milk¹ for the past 30 years or more. Some of the early tests would differentiate milk heated to about 70° C. or above from raw milk. The better known of these is that of Rothenfusser² designed to measure the effect of heat on the enzyme peroxidase. Modifications of this test^{3, 4, 5} based upon the effect of pasteurization on the enzyme diastase have been tried unsuccessfully as tests for pasteurization. Other tests for heated milk including the microscopic cellular test,^{6, 7} have failed to differentiate between pasteurized milk and milk undertreated in pasteurization. Some of these tests including the more recent amylase test as modified by Gould⁴ and by Leahy⁵ would differentiate, in our experience, between unheated milk and properly pasteurized milk but fail to show consistently dangerous degrees of undertreatment. Furthermore, on occasions our laboratory found amylase absent in samples of raw milk.

It seemed almost incredible that an enzyme could be found in milk that would lend itself to the purposes of a

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

test for pasteurization, that is, would be always present in raw milk in abundance and would be almost completely devitalized by the heat treatment required for the pasteurization of milk. Phosphatase is such an enzyme.

The test was developed by Kay and Graham.⁸ Reports from England indicating its successful use led us to try it out. In our work we have used a modification by F. W. Gilcreas⁹ in which color comparisons are made in test tubes instead of by tintometer. The technic has been reported elsewhere⁹ but a brief statement of the principle involved is in order. The test is based upon the action of the enzyme phosphatase which is present in raw milk but is almost completely devitalized by pasteurization, on a buffer substrate containing disodium phenol phosphate, Folins reagent being also added. During incubation for from 18 to 24 hours at 37° C., phenol is liberated in proportion to the amount of phosphatase present which after clarification of the sample is read by comparing the intensity of the blue color in test tubes with that produced by known concentrations of phenol or with permanent standards. Controls are used.

Preliminary tests with this technic on prepared samples unknown to the examiner indicated that the test will show as undertreated (a) milk held at 143° F. for 25 minutes, (b) milk held for 30 minutes at 141½° F. and (c) pasteurized milk to which as little as 0.1 of 1 per cent of raw milk had been added. Of course the test will not tell which of these three things has happened.

The New York City Department of Health has developed and used two other modifications of the test, one a quick test for field use, and the other a modification in which the samples are incubated for only 1 hour instead of from 18 to 24 hours and in which Gibbes reagent has been substituted

for Folins reagent in the determination of phenol content. Considerable comparative work is necessary before we can say whether one modification is superior to the other.

Our experience in the practical use of the test as well as that of other health departments has been favorable, indicating that the test has great possibilities. A critical trial of the test through the examination of split samples by a group of coöperating laboratories throughout the country is being undertaken under the direction of the Association of Official Agricultural Chemists with a view to having it adopted as a standard method of milk analysis.

In New York State we have examined since 1935 more than 2,000 samples of pasteurized milk and cream. Notwithstanding our previous work in the inspection of pasteurizing plants and in the examination by standard plate count and coliform test of process samples collected at such plants, we found that 8 per cent of samples examined by the phosphatase test were actually raw, and another 21 per cent of samples indicated undertreatment or the addition of raw milk to pasteurized. A total of 632, or about 29 per cent, of the samples were unsatisfactory. In every instance follow-up inspections at the plant resulted in either (a) the operator admitting what had happened to cause undertreatment, (b) our inspector otherwise securing evidence of what was wrong, or (c) in a few difficult cases in our demonstrating that samples processed in what was claimed to be the usual manner but in the presence of our inspector gave properly pasteurized reactions when examined by the phosphatase test.

A review of some typical examples of violations that were found should be of interest.

In one instance the operator was not convinced of the necessity for pas-

teurization and admitted that he bottled raw milk and labeled it pasteurized.

In another instance the dealer sold raw milk to a plant and bought bottled pasteurized milk which the test showed was properly pasteurized. However, a sample of his pasteurized cream gave a raw reaction. He admitted separating some raw milk from his own herd because he only needed a small amount and this was a cheap way of getting cream which he thought had better viscosity than the pasteurized cream he could purchase.

At another plant, the recording thermometer registered $1\frac{1}{2}^{\circ}$ F. higher than the indicating thermometer, resulting in underheating the milk by that amount although it had checked correctly at the time of the last previous inspection.

Still another investigation showed that the recording thermometer clock ran fast, showing 30 minutes holding when actually only 25 minutes had elapsed.

At one plant our investigator found a 24 hour chart was incorrectly used on a recorder built to use 12 hour charts resulting in 15 minutes holding when 30 minutes was shown on the chart.

A potentially dangerous situation resulted when a boiler flue burned out and after unsuccessfully trying to have it repaired in time for the next day's run the dealer took a chance on selling the raw milk. We chanced to collect a routine sample of the milk and detected this by the phosphatase test. He claimed it was the first time this had happened in his 13 years in business.

In following up another unsatisfactory result our investigator found that the operator had forgotten to close the outlet valve before filling the pasteurizer, permitting unpasteurized milk to fill the outlet line as far as the milk pump.

Still another investigation showed

that a leak protected outlet valve of the older type was left in a closed position in which the mating grooves were not mated, permitting underpasteurized milk to enter the outlet line.

In a number of instances operators pushed charts by hand from 5 to 15 minutes, thus cutting the holding period at pasteurizing temperature that much to save time.

In several instances raw milk was added to 40 per cent pasteurized cream to make 20 per cent cream.

Another investigation showed that properly pasteurized milk for sale in bulk was placed in a can from which raw milk had been dumped without subsequent washing and sterilization.

One of the more difficult investigations showed that properly pasteurized milk remaining in the pipe lines and bottler when bottling was finished was drawn off in a can that had contained raw milk but had not been subsequently washed and sterilized and was thence dumped into the separator. The cream made from this milk gave an undertreated reaction.

In a large cream plant an interconnection existed in the complicated milk piping to permit raw cream to be cooled over the same surface cooler used for pasteurized cream of which a number of samples gave an underpasteurized test.

One thrifty but poorly informed plant operator caught the drippage of underpasteurized milk from a leak protector outlet valve in a can cover and emptied it into the batch of properly pasteurized milk.

Our investigators found that the undertreated reaction on pasteurized milk at one plant was due to failure to operate the agitator in the small pasteurizer during holding. Milk near the outlet valve was found to be about 5° below pasteurizing temperature. The operator said that he did not use the agitator during holding because when

he started it the temperature dropped on the recording thermometer chart.

Last and perhaps most interesting, the phosphatase test gave a raw reaction on a sample of milk from a 40 quart can at one of two children's camps in which simultaneous outbreaks of gastroenteritis occurred last summer. An investigation at the pasteurizing plant furnishing milk to both camps showed that cans of unlabeled raw milk were stored in ice water in the same vat with unlabeled cans of pasteurized milk. It was evident that a can of raw milk had been either accidentally or wilfully delivered to each of the camps in place of pasteurized milk.

The phosphatase test also has been used extensively during the past year by our two greatest cities—New York and Chicago. The Department of Health of New York City reports having made in excess of 10,000 tests. Similarly the Health Department of the City of Chicago reports having made thousands of tests by the unmodified Kay and Graham technic. Both departments have found enough under-treated reactions to convince them of the value of the test.

Reports also show that the test has been used during the past year by the City Health Departments in Jacksonville, Fla., and Utica, N. Y., and by the Westchester, Cattaraugus, and Tompkins County Health Departments in New York State. Undoubtedly other health departments not heard from also are using the test.

It is not reasonable to assume that conditions in pasteurizing plants in New York State or in New York City or

Chicago are much different from those in plants in other sections of the country. Those conditions might have been more serious if it were not for the facts that (a) all raw milk is not infected, and (b) pasteurization provides many factors of safety in both temperature and holding time.

Experience in the practical use of the phosphatase test for pasteurization convinces us that it has great practical value. Although continued use may reveal interfering substances, no serious interference has been encountered to date. Those health officials who recognize the importance of pasteurization of milk to public health and their responsibility to the public to see that milk and cream so labeled are actually pasteurized will welcome this test.

DISCUSSION

PAUL F. KRUEGER

Director, Bureau of Dairy Products, Board of Health, Chicago, Ill.

UNDER the personal direction of Dr. Herman N. Bundesen, the Chicago Board of Health has been interested for a number of years in developing a suitable test or tests for determining the efficiency of pasteurization. Working independently, and also in an attempt to evaluate the practical value of various tests contained in the literature from time to time, it was found that the so-called "enzyme" tests had the greatest possibilities for this purpose.

Our early work done in connection with the phosphatase test followed the suggestion of the New York State Department of Health that by this method it was possible to determine quite small irregularities in the pasteurization process.

It was found early in our experimental work with the phosphatase test, that it indicated that a much greater amount of milk and cream was improperly pasteurized than we believed was actually occurring. True, in many of the first cases found, it was possible to discover and correct defects in plant practice when the phosphatase test indicated improper pasteurization. In some of the instances, however, in which the test indicated improper pasteurization, it was very difficult if not impossible to find the unsatisfactory conditions. It was essential, therefore, that sufficient work be done in the field to establish definitely the correlation between test and actuality.

If the phosphatase test was to be an important part of our milk control program, we must have the assurance that when samples were found bad, there was a corresponding error in operation somewhere that must be corrected.

It was early established that the use of the phosphatase test, as originally detailed by Kay and Graham in their "B" test, gave satisfactory results in the laboratory. This test was operated purposely without modification, an 8 hour incubation period being used to correspond to our required pasteurizing temperature of 144° F.

Routine tests were made by this method of the thousands of samples of milk, and of cream and other milk products collected for chemical and bacteriological analysis in the City of Chicago from every plant under our supervision.

For months painstaking work in the field was done to determine what factors, if any, may affect the accuracy of the test. Without detailing this work, the following conclusion summarizes our results: Pasteurized milk handled in accordance with our requirements will have a blue color lighter than 2.3 lovibond units when subjected to the phosphatase test as described by Kay and Graham (*Journal Dairy Research*, May, 1935).

A color intensity of 2.3 lovibond units or more definitely indicates that:

1. The milk has been insufficiently heated;
2. The milk has been insufficiently held; or
3. Raw milk has been added to the pasteurized milk during the holding period or thereafter.

The number of units above 2.3 indicate approximately the seriousness of the violation.

The test may be applied to milk, skim milk, soft curd milk, vitamin D milk, homogenized milk, goat milk, cream, and ice cream mix. It is not wholly satisfactory for chocolate or cocoa milk and beverages, and for ice

cream to which certain colors and flavors have been added.

The reason so much time was spent by the Board of Health in determining the actual efficiency of the test was the fact that a considerable number of samples of milk and milk products were at first found to be improperly pasteurized, the cause for which we were at a loss to understand. This difficulty was due mainly to our reluctance to believe that so many milk plant employees would rather pasteurize fraudulently than do the work properly. It was soon established, however, that the greatest number of cases of fraudulent pasteurization was due to the faking of the pasteurizer chart by the employee operating the pasteurizing equipment.

The reason it was so difficult on our part to determine fraudulent "pulling" of charts was, first, that the use of air space heaters on all milk pasteurizer vats has made it possible for the plant operators to make a straight line on the chart during the holding period. Previous to the use of these heaters the line would normally vary noticeably throughout the holding period so as to make it easily possible to detect a fraudulent chart. Secondly, during most months of the year the raw milk before pasteurization is lower than the 30,000 bacterial standard for pasteurized milk, so that an excessively high plate count did not always result.

When asked why charts had been tampered with, the pasteurizer operator replied with such reasons as, "I wanted to hurry to get through." "I had too much work to do." "I wanted to quit early because of a holiday or Sunday." It is interesting to note that more than 80 per cent of the illegal samples were found to have been pasteurized on a Sunday or a holiday.

In order to overcome this tendency on the part of operators to make fraudulent pasteurizer charts, it was re-

quired that every recording thermometer in the pasteurizing plants under our supervision be modified so that the center hub of the instrument would have attached to it two or more pins to which the chart may be fastened. Should a chart be fraudulently moved, once it has been set on an instrument so equipped, there would either be a tear in the chart at the pins, or a duplicate set of perforations would be made which could be easily detected. This improvement, which was readily provided by all the instrument manufacturers at our request, has proved to be very satisfactory.

Another trick that a dishonest operator may resort to is to open the pasteurizer valve before the end of the 30 minute holding period. We are working at present with the recording instrument manufacturers with a view to installing additional pens or other devices on the recording thermometer which will record the closing and opening of the inlet and outlet valves of the vat or pocket pasteurizer.

In addition to the fraudulent pasteurization described, it was found in other instances that milk was improperly pasteurized although the operator did not know such a condition existed. Some of the reasons found in these instances were:

1. The outlet valve of the pasteurizer vat was not fully closed before the inlet was opened.

2. The raw milk inlet valve to the vat was not fully closed or was leaking.

3. The pasteurizer outlet valve was not fully closed.

4. The use of the same equipment and containers for pasteurized milk as for raw milk without thorough cleaning and sterilization between usages.

5. When small batches are pasteurized in a large pasteurizer, at times the indicating and recording thermometer bulbs do not reach the liquid and so record air temperatures. When air-space heating equipment is used the result is that considerably higher temperatures are recorded than the product actually reaches.

Automatic equipment has been found singularly free from pasteurization defects. Perhaps this is due to a great extent to the fact that all automatic heaters are equipped with pump stop control devices, which we have found to be singularly free from mechanical operating difficulties. Only two instances were found of improperly pasteurized milk in such equipment, and the cause of both of these errors was also readily discerned from an examination of the recording thermometer charts.

We are at present conducting a series of experiments in the application of the phosphatase test to butter and to cheeses of various types. Inasmuch as age and degree of refrigeration seem to affect the results of the test in connection with these products, no definite conclusions

are possible at present. The value of a satisfactory test of this nature when applied to these products should prove of inestimable value to the health officer.

In conclusion, it may be said that the upper limit of the phosphatase test has been set low enough so that the enforcement official may be sure there is need of correction whenever that limit has been reached or exceeded.

The application of the phosphatase test will not do away with the necessity for pasteurization plant inspection. Effective inspection work must be continued just as before if we are to be assured of proper plant operation at all times. The phosphatase test should be looked upon as an additional weapon in the hands of the health officer in his work of milk sanitation enforcement.

SOL PINCUS, C.E., F.A.P.H.A.

Deputy Commissioner, Department of Health, New York, N. Y.

WE, in New York City, have long hoped for a positive test to determine the occurrence of improper pasteurization of milk and cream. Three years ago our department experimented with the amylase test which we then applied in special investigations. This test, which was highly recommended at that time, gave promising results.

In August, 1935, about 6 months after we had begun work with the amylase test, we found the reference to the Kay and Graham phosphatase test in the reports of the British Ministry of Health. However, we encountered difficulties in obtaining the required chemicals for the phosphatase test, and since the first results with the amylase test showed promise, we put aside investigation of the British test.

When the series of comparative tests which were undertaken in cooperation with the State Department of Health to determine the value of the amylase

test proved that there were some difficulties with this test, we at once proceeded to make a thorough investigation of the Kay and Graham phosphatase test on a large scale. Several modifications of the standard British tests were tried by our laboratory to simplify the procedure and shorten the time for obtaining the result. As a consequence of this study, we found it advisable to replace the veronal buffer used by Kay and Graham with a borate sodium hydroxide buffer and to purify the substrate diphenolsodium-phosphate so as to remove the residual phenol. Through the substitution of a more sensitive phenol detecting agent, namely, 2,6 dibromoquinonchloromide (a reagent similar to the one used in the Gibbs test for phenol in water), we were enabled to reduce the time to a 1 hour incubation period and still retain an accuracy comparable to that of the Kay and Graham technic requiring a 24 hours incubation.

A further modification permitted the use of this procedure as a quick field test by the inspectors, requiring less than 20 minutes.

The accuracy of the laboratory method with the 1 hour incubation is such that we can detect a drop of 1°F . in temperature, a shortening of the holding time of 5 minutes, or the addition of $1/5$ to $1/2$ per cent of raw milk through leakage or through any other defect. The field test will detect a drop of 2° in temperature, a reduction of holding time of 10 minutes, or the addition of 1 per cent of raw milk.

Since the substrate has a tendency to decompose on standing or ageing, we have developed tablets for both the necessary solutions, namely, the buffer substrate and the buffer reagent. This makes it possible for an inspector in the country to be supplied with material from which he can make fresh stable solutions.

Our field test, we believe, is a significant innovation, as improperly pasteurized products may be detected at the plant or railroad yards by our inspectors, who can thereby prevent the marketing and consumption of such products.

The field test has also a psychological and educational value. The plant employee or the plant operator, having seen that the inspector can detect the presence of improperly pasteurized milk, will be more careful that the products are fully pasteurized. It is also more convincing to see the results of a test run at the milk plant than merely to receive a verbal or written notice to the effect that pasteurization operations were not correctly performed.

All samples delivered to our laboratories for chemical or bacteriological analysis are also being tested routinely for pasteurization. Whenever our laboratory tests show irregularity involving a country pasteurizing plant, the

plant operator and our district inspector are notified of the findings. Our city inspectors are immediately assigned to meet the truck or train bringing the product into New York City that day. The field test is performed for pasteurization, and samples are submitted for laboratory test. An abnormal reaction on the field test results in the embargo of the product, which is released only for manufacturing purposes and after repasteurization. At times we find it necessary to exclude plants immediately as a source of milk supply and cream supply for New York City on the basis of our phosphatase test findings. Such plants are kept out until there is sufficient proof that the irregularity has been corrected.

The procedure is similar when city pasteurizing plants are involved, except that our inspectors can be dispatched to the plant within a short time to test the product stored there, and to check the pasteurizing operation.

During the period from April 1 to September 20, 1937, our department examined by this test, 10,635 routine milk and cream samples brought into the laboratories for chemical and bacteriological analyses. Five hundred and fourteen or 4.7 per cent, showed evidence of irregularity in pasteurization to a lesser or greater degree.

During this period we also examined 1,081 samples of milk and cream which were collected from suspicious sources, and of products indicated by our routine tests to be improperly pasteurized. Two hundred and fifty-seven, or 23.77 per cent, of these samples which were collected specifically for pasteurization test were found to be not fully pasteurized.

In addition, our inspectors also applied the field test to about 2,000 samples of milk and cream, finding 219 to be improperly pasteurized.

Some of the more common defects disclosed at the pasteurization plants

as the result of our phosphatase test findings, were as follows:

1. Standardization of fully pasteurized cream with raw or improperly pasteurized skim or whole milk was taking place. In some cases the practice was to standardize the pasteurized cream in the can by scooping out a few quarts of cream from the can and replacing it with skim milk, or milk which was raw, such as certified milk dumped from bottles returned by routes.

2. Recording thermometers were incorrect and registered too high a temperature. In one instance we found the bulb of the recording thermometer resting on the bottom metal portion of the tank, causing the registration of a 4° higher temperature than the actual temperature of the product in the pasteurizing tank.

3. Leaks from the outlet valves of the pasteurizer occurred during the filling and holding period, permitting the seepage of raw or partly pasteurized product into the outlet pipe.

4. Excessive foam was found on the surface of the product in the pasteurizer, held at a temperature less than 143° F. in the pasteurizing process.

5. Agitators were not used during the holding period, causing in some types of equipment, a portion of the milk to be below 143° F.

6. Pasteurized product was run over coolers and over equipment previously used for raw product, without adequate washing and sterilization after such use.

7. Holding of product in the pasteurizing process at 143° F. took place for a period less than 30 minutes. Frequently, this irregularity could not be determined from the recording thermometer due to the time element involved in filling and emptying the tank.

8. Inexperienced pasteurizing operators were substituted during illness, or for other absence of the regular operator. Such operators frequently do not turn the inlet or outlet valve in a correct position to close the inlet and outlet of the pasteurizer fully during the holding period, with the result that some raw product enters the holder, or some not fully pasteurized product enters the outlet pipe of the holder.

In one instance where a continuous long-flow pasteurizer was in use, we found that the electrical pump which was to force the milk through the pasteurizer at a definite rate had been sub-

stituted by a steam pump. The rate of flow was irregular and apparently above the permitted capacity of the pasteurizer.

As the result of these findings, we are emphasizing the following requirements:

a. That cream be standardized before pasteurization.

b. That the operator check the recording thermometer daily and that the result of such check be indicated, in ink, on the recording thermometer chart, with the signature of the employee making the thermometer observation.

c. That inlet and outlet valves be examined as to possible leakage.

d. That efforts be made to reduce the foam on the surface of the product during pasteurization.

e. That agitators in pasteurizing holders, which are not properly insulated, should be used during the holding period.

f. That separate equipment be provided for the handling of the raw products, and for the handling of pasteurized products.

We feel that to eliminate the possible irregularity due to the inexperienced or careless operator, it would be desirable to require that all pasteurizing equipment be automatically controlled as to temperature and holding time.

I believe that the phosphatase test represents one of the greatest developments in milk control since the inception of pasteurization. It is amazing that one can as the result of this test determine in New York City that the pasteurizing equipment is not functioning properly at a country plant 200 or 300 miles away, or that the employee in charge of the pasteurization has hurried the operation, or otherwise failed to pasteurize the milk or cream properly. A forecast of the great significance of the phosphatase test was made by Governor Herbert H. Lehman before the American Public Health Association convention on October 5 last, when he stated that it "bids fair to revolutionize milk control policies throughout the United States."

Nutritional Influence on Teeth*

FRANCES KRASNOW, PH.D.

Assistant Director and Head, Department of Biochemistry, School for Dental Hygiene, Murry and Leonie Guggenheim Dental Clinic, New York, N. Y.

THE title is not intended to convey the idea that tooth conditions are affected very specifically by the intake of certain foods entirely independently of others which are required by the body generally. Recent research is fast reverting to the original concept that the complex organism is a unit entity. Dental health is no less a resultant of those conditions which make for the health and life of the body as a whole than it is itself one of these factors.¹

Only the balanced diet (including proper supply of oxygen) will meet the food requirements for absolute health—be it tooth health, ear health, eye health, the health of any other organ or group of organs, or the general health of an individual. Since life begins *in utero*, the foundations of normal well-being depend upon the supply of the essential materials made available through the mother—the health of the latter not being of lesser importance.² Furthermore, the balanced diet should be viewed as part of a complete medicodental clinical and laboratory examination. It should be interpreted as a variable depending upon: (1) age, (2) sex, (3) body build (especially weight and height), (4) occupation, (5) cli-

mate (season, immediate atmospheric environment), (6) physiological state; i.e. (a) extent of freedom from physical and mental fatigue based on the hours of rest essential to take one through the daily tasks without the feeling of being tired; (b) extent of freedom from disease, be this due to metabolic malfunction, *per se*, parasitic invasion, or poisoning by toxins of varied nature other than those arising from infection.

These factors determine both qualitatively and quantitatively the make-up of any dietary and, broadly considered, diet regulation is only part of a comprehensive scheme to bring about scrupulous individual hygiene and in turn controlled community hygiene.

A balanced diet may be defined as one which supplies the body at the *required rate* with the proper quantity of substances necessary to build and repair tissues and create heat and energy. The substances may be classified conveniently as (1) proteins including all essential amino acids, (2) lipids including all essential fatty acids, (3) carbohydrates, (4) minerals, (5) vitamins, (6) water, and (7) roughage. Indeed the correct quantity of each food class does not necessarily mean the correct quantity of the essential nutrients. It is extremely important to safeguard the several innate qualities which any foodstuff represents:

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

1. At the source of production—Thus, milk from healthy cows grazing in good pasture is richer than that from cows fed on dry, carelessly mixed feed; also, vegetables from different soils differ markedly, as for example, those from soils watered by sea water will contain iodine whereas those from soils in fresh water regions are practically devoid of this essential element.

2. By correct preservation before reaching the consumer—The responsibility of obtaining only carefully preserved products, in good part, falls upon the consumer. Precaution in purchasing new brands will help a great deal toward freeing the market of poor varieties.

3. By preservation by the consumer.

4. By proper preparation—The chief error in this regard is marked overcooking, frequently in uncovered containers and with a large quantity of water which is usually discarded. Such methods deplete the foods of the very properties for which they have been selected—vitamins lose their effective characteristics entirely, or at least to a large extent, due to excessive heat and oxidation; the minerals dissolve when excess water is used, and if poured off as waste leave the particular foodstuff less valuable as a nutrient source. The end result is inferior food with inevitable poor nutrition and ill health either of the organism as a whole or of one or more of its organs. This leads to increased expenditure for upholding health standards.

Food value is not always proportionate to price. Thus, the high cost purified foods should really be regarded as delicacies and for low income groups must be omitted entirely. Witness also, the favoritism for white-shell eggs as compared with the much less expensive brown-shell ones; or, pure white tightly packed lettuce instead of beet tops.

Variety is frequently stressed as a rule of thumb for obtaining a correct dietary. There is no doubt that greater adequacy may be secured, and if guided by accepted standard requirements daily menus can be arranged which would apparently be commensurate with the needs for normal metabolic activity; yet recent investigation finds that even good combinations may be unbalanced.

Researches on the quantitative salivary analysis of individuals suffering

from caries or erosion indicate characteristically different chemical pictures of saliva for different dental conditions.⁵ Chart I summarizes some recent data. The analytical figures have been tabulated to show average values, incidence above the average normal range, and odds against random occurrence of deviations from the normal. Thus for erosion, the average hydrogen ion concentration, calcium, magnesium, inorganic phosphate, protein, lipid phosphorus (otherwise called alcohol-ether soluble phosphorus and lecithin) or cholesterol lies entirely beyond that for the same constituent in saliva of normal individuals. Compare the values 6.83, 7.6, 0.75, 18.0, 446, 0.52, 11.2 respectively with 7.14, 6.3, 0.46, 15.2, 298, 0.13, 7.5. The standard deviations are relatively small. None of the average ranges overlap, hence variations from the normal are probably significant. There are apparently two types of erosion, each with a specific salivary composition. One with alkaline saliva yields markedly lower concentrations: hydrogen ion, calcium, magnesium, and protein approach the normal; inorganic phosphate and cholesterol fall below, lipid phosphorus above. The other presents an acid saliva with much higher levels—6.73, 8.2, 0.84, 19.7, 489, 0.60, 12.9 for the analyses in the order listed instead of 6.83, 7.6, 0.75, 18.0, 446, 0.52, 11.2 respectively.

If instead of averages, the distribution with respect to the average normal range be considered, there appears a very high incidence of cases above the high normal level. It is noteworthy that for each analysis, the concentration exceeded the high normal figure in more than 50 per cent of salivas from subjects suffering with erosion. Again, the figures are accentuated for the acid subgroup. Compare 87, 87, 60, 80, 86, 65 with 74, 68, 53, 68, 78, 57 respectively for the percentage of cases yielding salivary calcium, mag-

Normal values obtained from analyses on subjects who as far as medico-dental clinical and laboratory tests could discern had no ailments—pH: 7.14±0.04, Calcium: 6.3±0.4, Magnesium: 0.46±0.07, Inorganic Phosphate: 15.2±1.0, Protein: 298±17, Lipid Phosphorus: 0.13±0.02, Cholesterol: 7.5±0.7.

* Erosion refers to subjects suffering from wastings: erosions or abrasions.

† Caries refers to subjects with active decay processes only.

nesium, inorganic phosphorus, protein, lipid phosphorus and cholesterol above the high average normal content, again pointing to the probability that the variations are real. Finally, computations for odds against the chance occurrence of differences for the acid group yielded odds greater than 4 for all substances studied and so the suggested statistical significance is verified a third time.

In caries-active individuals variations from the normal are fewer—non-overlapping figures appearing only for pH, magnesium, lipid phosphorus and cholesterol, with values of 6.92, 0.65, 0.20, 10.7 respectively instead of 7.14, 0.46, 0.13, 7.5. Also for caries, there exist

apparently two distinct types—one with alkaline saliva, the other with acid saliva. The former presents a

reduction in inorganic phosphate from 14.4 to 12.6 (almost to the same level as in erosion associated with alkaline saliva: pH, calcium and protein remain normal but magnesium, lipid phosphorus and cholesterol are high. On

the other hand, differences from the normal are enhanced in the acid saliva subgroup. The pH is depressed to 6.71, magnesium, lipid phosphorus and cholesterol are increased to 0.73, 0.22 and 11.9. Evaluation of the analytical figures by ascertaining the percentage incidence or the odds against randomness showed the same close agreement of the different statistical methods which was indicated for the erosion studies.

It seems plausible to assume a common mechanism at work. The results imply a tendency to that type of derangement often associated with acidic states in the body, notwithstanding that the subjects, for the most part, had no other pathological involvement as far as the usual medico-dental clinical and laboratory tests could discern. Detailed perusal of accumulated data, coordinated with the fact that the organism makes every effort to rid itself of acids in salt form, led to the examination of the dietary acid-base potentialities in addition to the usual orthodox factors.^{1, 14, 15}

In the plan adopted¹ the chief criteria of physiologic response are subjective guides, clinical manifestations (roentgenograms), weight changes and variation in the chemical composition of saliva. To insure saliva samples

which are duplicable and representative of an individual, conditions are set for a definite metabolic plane over at least one week preceding any analyses. They include (1) no recent mishap or illness, (2) thorough brushing of the teeth and washing of the mouth just before retiring the evening preceding each test day, (3) 8 hours sleep during the night prior to each test day, (4) no brushing of the teeth or rinsing of the mouth nor having breakfast (water) or smoking on the morning of each test, (5) a 1½ to 2 hour interval between rising and collections, this interval including a 15 minute rest period at the laboratory, and (6) a detailed record of meals.

Each patient receives the diet booklet represented in Chart II. The pages are individually dated or otherwise marked when necessary. This is returned the morning of the laboratory appointment and filed with Charts III and IV which have been filled out by the dentist.

Samples of saliva are obtained under the standardized conditions outlined. First, a small sample (about 1.0 c.c.)

is collected by spontaneous flow for the determination of the pH, which is carried out immediately.⁸ Then a large sample (40.0 c.c.) is accumulated with the aid of suction and a saliva ejector. As soon as this is completed, the patient is questioned to ascertain supplementary details noted on the original record card shown in Chart V. At this time a full set of X-rays is taken and a final check-up of the extent of tooth involvement is made. Aliquots of saliva are measured for the analysis of calcium,⁹ magnesium,¹⁰ inorganic phosphate,⁹ lipid phosphorus,¹¹ cholesterol,¹² and protein¹³ (Chart VI).

The weekly food intake recorded in the diet booklet is analyzed with reference to acidic factors (meat, fish, eggs, cereal, flour products), basic factors (fruits and vegetables with few exceptions), milk and milk equivalents, vitamins, water, and caloric intake (Chart VII). This probable habitual consumption together with the other findings assembled, as noted in Charts II-VI, is used to deduce the additional needs commensurate with the individual's requirements.

Finally a complete summary is prepared as in Chart VIII. The clinic or the dentist using our consulting laboratory service receives a copy of the entire report for filing and a carbon duplicate of the recommendations given to the patient.

As noted in Chart VIII, the diet is checked for the last week of each month. After the patient has carried out the suggestions for 4 to 6 months, another complete analysis is instituted. Chart IX indicates the return to the normal level of phosphorus (inorganic phosphate), magnesium, cholesterol, and lecithin (lipid phosphorus or alco-

hol-ether soluble phosphorus) within 4 months. There was no noticeable improvement in the dental condition at this time. Recommendations accentuated somewhat the decrease of potentially acid food varieties. Dental examination 6 months later showed interproximal decalcification arrested and no new cavities.

A sample menu which possesses the balance of nutrients used is presented

SUMMARY AND CONCLUSIONS

Concerted interest and action of physicians, dentists, and laboratorians is the keynote of success in health programs. Dental health is no less a resultant of the health of the organism as a whole than it is itself one of the contributing factors. The balanced diet if interpreted as part of a comprehensive scheme will aid greatly in bringing about scrupulous individual hygiene. To do this it is necessary:

1. To learn the detailed needs of the patient with reference to his entire make-up.
2. To recommend diet changes not in generalities but as specific and calculated prescriptions.
3. To institute frequent check-ups in order to obtain the patient's willing cooperation, for without it every effort will be of no avail.

Thus far, the procedure at the Guggenheim Dental Clinic is resulting in data which apparently indicate a nutritional influence on teeth and point to salivary analysis as an additional objective guide for directing the diet change.

CHART X

Sample Menu for Child of Five Years

Time	Food	Portion	Caloric† Total Value Calories
7:00	Water	¾ glass	
7:15	Cod liver oil	2 tsp.	75
	Cereal (whole seed)	½ cup	52
	Molasses	2 tsp.	60
	Milk (Grade B) *	1 glass	170
10:00	Carrot or beet * (raw twice a week—slowly increasing to greater frequency)	1	15
11:15	Water	¾ glass	
12:00	Potato	1 (medium)	100
	Beet tops (cooked 5 minutes in covered pot with no water added after washing). Green cabbage may be substituted. Raw greens introduced gradually.	⅓ cup	2
	Bread	1 slice	40
	Butter	1 tsp.	40
	Banana *	1	100
	Water	¾ glass	
3:00	Milk	1 glass	170
	Cookies ‡	2	50
6:00	Bean or split pea soup	½ cup	75
	Turnip or similar vegetable in season	⅔ cup	32
	Whole wheat bread (24 hours old)	2 slices	80
	Substituted by:		
	Fish (once a week)	2½ oz.	50
	Spleen, heart, lung meat, once a week *	2½ oz.	170
	Egg (Grade B), twice a week	1	75
	Butter	1 tsp.	40
	Fruit in season	1	75
			1,176

Candy, ice cream, rolls, fresh bread, cake must be excluded from diet. Total cost of diet is approximately 18-22 cents per day. The schedule may be applied to other non-school ages with proper adjustment of calories, etc.

* Extra milk, fruit or fruit juice, beef and liver desirable if income permits.

† Approximate values only.

‡ Three quarters glass of water now or at 4:30.

Practical Procedures in School Health Service^{*†}

DOROTHY B. NYSWANDER, PH.D.

Director of the School Health Study, Committee on Neighborhood Development, New York, N. Y.

HOW does an executive of any organization, public or private, find out whether his department is doing an effective job? This is a practical inquiry. Complacency and self-congratulation have little place in modern administrative jobs. The administrator must know to what degree he is successfully reaching his objectives. The question is—how to make the evaluation.

If the organization is large the executive has many departments. Each of these during the course of time has built up files filled with executive orders, statements of policy, bulletins, and manuals. These materials, each in its own special time, met a certain need. Many of these needs, however, belong to the past, for new concepts, new theories of procedures, new techniques, and new social forces have been introduced into the picture.

Besides the handicap of outmoded regulations there is the handicap of the attitudes of the staff for whom these regulations have become "sacred cows." Often, unfortunately, the "sa-

cred cows" of the various departments are tethered in widely separated fields. It becomes administratively difficult and expensive to give them the care they constantly need for survival. The executive of the division cannot keep watch over them. It is impossible for him to see that their services are no longer valuable and that their maintenance is depriving his modern organization of the sustenance and energy necessary to do the job.

He knows that a well trained staff and good physical equipment make for effective service. The executive in the field of education is aware, however, that good teaching is not synonymous with authors of textbooks or marble halls and stadiums. Nor is superior performance in public health necessarily associated with high-powered publicity, expensive clinical equipment, elaborate statistical records, or vast numbers of personnel. The test of an organization's efficiency lies in its total effect upon the end product. In education and public health the test lies in the degree to which changes in a positive direction have been made in the behavior of people.

If the administrator feels that his department is not effecting such changes, he wants to know why. Is it because of poorly trained personnel, lack of personnel, lack of facilities, or

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

† This study is sponsored by the Department of Health and the Department of Education. Its direction and administration are under the School Health Study Committee of the Committee on Neighborhood Health Development.

because the mechanics of the administrative system itself are so permeated with tradition and imperfections that neither personnel nor facilities can function?

Consider now the specific problem of investigating the effectiveness of the school health service. (For our purposes it matters little whether that service is furnished by the department of health or the department of education.) The administrator responsible for the service is confronted by the fact that he has at least five professional groups involved, each under its own professional leadership. These are the school physicians, the school nurses, the clinic personnel, the teachers, and the private physicians. Where shall he start?

Several courses are open. He may call in an expert to make a survey. He may use the School Hygiene section of the A.P.H.A. *Appraisal Form* to determine the degree to which the service is meeting certain standards. He may make a statistical comparison between the school health activities of his city and those of other cities. He may ask his supervisors to give him data from which new policies may be evolved. Any one of these methods gives the administrator needed information and is certainly far better than making no attempt at self analysis. They have, however, serious weaknesses.

First of all, the use of any of these methods fails to go below the surface of operations in the school health field.

Second, the validity of oral or written reports obtained from the supervisory staff is questionable. The reports are vitiated by complex psychological factors, common in this situation, such as (1) the desire to make a good impression; (2) the belief that the service actually is functioning as represented although no check has been made; (3) "wish ful-

fillment" which operates in such a way that desiring a given result and stating it as having been accomplished become identical in the mind of the person questioned; (4) "defense mechanisms" whose automatic functioning serves to preserve the *status quo* and to keep the "sacred cows" unharmed.

A third weakness lies in the unreliability and lack of usefulness of certain statistics in the school health field. Studies by the American Child Health Association show that physicians markedly disagree in their diagnosis of tonsil defects. The number of malnutrition cases found depends on the procedures used in examination and on the attitudes of the medical director. Figures on dental defects and their corrections are usually useless. Only when the original recordings are the result of a careful dental examination, and each child is seen repeatedly during a year can a true picture be obtained of the service being rendered. Even when the statistics are reliable they may not give the administrator the desired information.

The director of a division of school nursing may be interested in the average number of home visits made by a nurse during a given period, but she and the administrator rightfully raise the question "How valuable in changing health behavior were these visits?" Statistics do not answer this question. Statistics may show that a school physician examines 15 children or 50 during a morning. Neither figure gives the medical director or the administrator insight into the value of the medical services rendered or the type of educational job done with teacher, nurse, and parent in getting the child on the pathway to correction. In other words the statistics usually obtained, although useful for general administrative purposes, fail to reveal either the quality of work done or the specific places where the complex administra-

tive procedures fail to function effectively.

There is, however, another method available to the administrator, one that will give him information basic to developing a school health service in which medical, nursing, and educational staff can carry out the best modern theory and practices known in the school health field. This, for the lack of a better name, may be called the method of "administrative research." It is administrative in that it concerns itself only with problems whose solutions have direct bearing on the functioning of the service. It is research in that the methods employed in solving the problems are frankly experimental and that recommendations made to the administrator are outcomes of problems discovered, analyzed, and given trial in the field.

The larger the organization the more important it is that someone capable of independent and impartial judgment be detailed, not in the central office, but on the firing line to observe what is actually taking place, to sense the gaps and the impractical. Here is the place to work out smooth functioning. The administrator—whether director or supervisor—is usually pretty well occupied in keeping the engine running. He has neither the time nor the opportunity to delve or to cut and try. These opportunities for administrative research within the growing organization are believed to have practical values that equal the demonstrations of new activities.

This "administrative research" method is being tested at the present time in New York City for its effectiveness in aiding the Department of Health and the Department of Education to evaluate the present school health service and to develop a better one. One health district has been designated as the experimental area for this purpose. Here studies are

made, procedures are put on trial, and results are evaluated. The assistant superintendent of education for the area, the director of health education, the directors of the nursing and school hygiene bureaus, the director of district health administration and their respective field supervisors act in the capacity of advisers and censors. They suggest or approve problems to be studied; they make administrative shifts in procedures and policies that the experimental work may proceed; they consider the significance of the results of the experiments and, when conclusive, incorporate them in remaking city-wide policies. The entire value of the study depends upon the degree to which individual administrators of the divisions of the service are given aid in solving their own administrative problems.

This study in "administrative research" has been planned for a period of 4 years. In a school health service of the proportions of New York City this period is not long enough in which to explore and test the many phases of the work. One year of the 4 has passed. Examples of the problems studied and recommendations made during this period will serve to give an idea of the types of services this approach affords.

To learn, first of all, how existing school health records were being used was the first problem of the study. The monograph, "Physical Defects—The Pathway to Correction,"¹ states that "all health records must be vital." By this is meant, records which are accurate, cumulative, and subject to interpretation by teachers and nurses. Present and future medical attention for any child depends on such records. So does the much talked of rapport between teacher and nurse, rapport between nurse and parent, and between school physician and private physician. Poor records and lack of records mean

poor service and lack of coördinated service.

The exploratory work on the problem of records was confined to one large school in the experimental area. Samples were taken of all available health and medical records for the following grades—kindergarten, 2nd, 5th and 7th. The analysis of the records revealed answers to the questions: (1) How complete are the medical files for children now in school? (2) Is the system now being used efficient in transferring school medical records from school to school for the constantly moving school population? (3) Do teachers and nurses in their separate reports indicate that they individually or together are following up defects for the same children? (4) Are the dental, eye, and cardiac clinical records entered on the regular school health record? (5) What use is made by the medical staff of teachers' written observations or reports on health conditions? (6) What use is made by the teachers of the medical records kept by the school medical staff? (7) To what degree do the medical cards give *differentiated* or *individualized* recommendations as to the "follow-up" procedures to be used? (8) Are the entries on the cards readable and understandable by nurse and teacher?

It had been assumed that records followed a child from one school to another when he moved. Actually, it was discovered on investigation that a surprisingly large number of record cards did not move on but died in a terminated file in the last school attended. And in some schools from 30 to 50 per cent of the pupils move annually. This situation called for a simple yet laborious job of revamping the files for ready reference and devising a practical plan for moving cards along with the children. This involved

- (1) providing a cumulative health

- record card for every child, which would go with him into the secondary schools;
- (2) instituting a more precise and accurate filing system of medical cards so that teachers may have available at any time the medical records for their grades;
- (3) sending the medical cards at the beginning and end of each term to the classroom teacher that she may be aware of the health problems known to physician and nurse, and that she may note on the card the grade and room to which the child is being transferred.

Serious lack of agreement in the knowledge of defects between teacher and nurse was revealed. Independent action was being taken on the same child. An experimental study was started immediately to determine the best way to coördinate this knowledge. The Department of Education in New York City has for many years asked its teachers to report twice yearly concerning the physical defects of the children. This report is made on a Health Day Sheet. In the experimental school this Health Day Sheet was changed so that teachers, instead of reporting *diagnoses* of defects, reported on the presence of *behavior symptoms related to health*. Pediatricians believed these symptoms would furnish important case history data to the physician making the diagnosis. To evaluate the teacher-references on this new basis and to test the value of the individual symptoms reported by the teacher became a major project. Eight classes comprising 300 children were selected for the evaluation. The results showed that teachers did not "swamp" the medical office with children. They referred children for medical attention who needed it. Only 10 per cent of those referred were found by the physician to have no defects. The error of reference lies in the cases *not referred* for medical attention. Of the 100 children in this

group 25 were considered by the examining physician to have some defect meriting immediate attention. Further checking during this next year will show whether or not the defects of these 25 children would be lost from sight altogether by this reference method or whether they would come to attention later through referrals by subsequent teachers.

The experimental evaluation showed too the weaknesses of the various symptoms on the Health Day Sheet and indicated specifically where stress must be placed in developing a new Health Day Sheet and in educating teachers to its use.

The study had less objective results but equally important ones. It showed that in using the teacher as a primary screen, (1) knowledge and reports of defects by teachers and medical staff become identical; (2) the physician has a personal professional interest in the child examined because he feels that a *need* for the examination has been expressed; (3) an avenue is opened wide by means of which the school physician and the school nurse may, through their subsequent conferences with the teacher, instruct her in making more valid health observations of her children, inform her as to the recommendations made to the parent concerning each defect; and gain her cooperation. In addition, these same conferences serve the purpose of bringing to the medical staff the instruction it needs in becoming aware of the emotional, social, and educational life of the child. Such information is necessary if the school health service is to meet the objective of really educating child and parents. This objective must not be neglected nor ignored.

Plans for next year call for an extension of these procedures with the new Health Day Sheet to 7 other schools differing widely in economic status. Each of these schools offers

different administrative problems affecting the objective of bringing the teachers and medical staff into a close working relationship. Not until such testing is done can recommendations for administrative changes be made.

Minor investigations were made of the efficacy of various notes embodying requests to parents concerning the child's health. It is generally agreed that placing a child, when possible, under the supervision of the family physician is a desirable objective of the school medical service. In the usual program the administrator formulates a letter urging the parents to have the child examined by the family physician. This letter may or may not be successful. Experimental work with different types of letters showed that whereas 15 per cent of the parents complied with the request for one type of letter, 65 per cent complied with another type. Similarly a good health service implies that the presence of the parents is desirable at all medical examinations given in the school; it further assumes that in many situations parent-nurse conferences in school are more satisfactory than nurse home visits. After trying out several types of notes to parents urging them to be present at the examination or to come to the school for a conference, two were selected. One of them brought 50 per cent of the parents to the school for the examination; the other succeeded in bringing 75 per cent of those not attending the examination to the school for conferences. Thus, with approximately 85 per cent of the children examined in school, immediate contacts were made with the parent in initiating remedial work for the child.

It has been assumed that certain routines when followed by a dental hygienist bring results. No measures of the amount of effort to achieve these results have been made in earlier studies. In order to estimate this

effort, 200 7th grade children were selected for a study. The following routines were carried out in the order given. First the child's teeth were examined and a notice was sent to the parents; the child was then seen by the dental hygienist 3 times at regular intervals to ascertain what was being done; next a special request was sent to the parents urging them to come to the school for a conference; finally, the child was referred to the assistant principal. Any child placed under dental care at any one stage of the routine was naturally not carried through the other stages. Detailed records give a measure of the amount of effort required to get a child's teeth corrected or under treatment. The study gives, too, an index of the problems encountered with children who failed to place themselves under treatment even when all of the above "follow-up" technics were employed.

A school health program always includes "follow-up" procedures. These may be of several types, such as conferences with parents at school, home visits, notes sent home, and instructing and re-checking the child in school. How effective is any of these methods for a special type of defect? To answer this question, at the conclusion of the year a study was made of the 2,400 medical records in the experimental school to find out the *types* of "follow-up" work done with parents and child by physician and nurse which had least success in getting medical attention for the child. Considering each defect separately an analysis of the "follow-up" work shows immediately that certain procedures bring few if any results, and that "follow-up" policies must be different for different defects. Experimental work during the

coming year will furnish answers as to what these procedures should be.

Even in the simple problem of getting Mary Smith to the dentist at least 7 people are usually involved—the school physician, the school nurse, the teacher, the two parents, the private dentist, and Mary herself. And the number of interrelationships between these people is many more than 7. It is only when a realistic attitude is taken toward complexities such as these, so that these interrelationships are recognized and appreciated, that Mary Smith will finally get her teeth filled, her glasses re-checked, and eat her breakfast before running to school. To demand efficient functioning of these detailed steps for one Mary Smith may seem too meticulous. It is indispensable for good administration when there are thousands of Mary Smith's.

Certainly, then, the complexities of the school health program suggest that no schema conceived in *a priori* fashion will work satisfactorily when it is put into operation. Here as in other complex problems of social welfare in which many different people work, many different agencies are concerned, many different types of people are to be served, the job calls for developing the program from the ground up, not from the top down. There is room for much more study of what may be called "internal management" within the school health service. This type of activity may be the best means of meeting some of the shafts of criticism that have been directed against the school health service.

Education of the Handicapped Child*

BRONSON CROTHERS, M.D.

Children's Hospital, Boston, Mass.

THE term handicap at once suggests disease or disability and tends to establish medical control. On the other hand, education suggests the orderly development of assets, and teachers are necessarily looking at what is left rather than what is gone. There is no possible use in a discussion unless it is recognized that training of doctors is very different from that of teachers and that effective coöperation is dependent on understanding of necessarily divergent attitudes.

For the purpose of this discussion the term handicapped is limited to the group of children with disabilities dependent on damage to the motor machinery of the body; in other words, the group which is frequently referred to as the cripples. This definition leaves out of consideration the blind, the deaf, and those whose disabilities arise from disturbances of mental and emotional equipment.

Everyone of this restricted group comes first under medical scrutiny, so that the doctor's decisions and his attitudes are of enormous importance. It seems to me very clear that the medical attitude at the start is one of the things which influence the whole educational process, and some understanding of it must precede further discussion.

Traditionally the physician tries to

arrive at a clear understanding of the following aspects of a case.

1. The status of the child at the time of examination. Primarily this is expressed in terms of deficit. This insistence upon deficit or disturbance, either anatomical or physiological, is entirely inevitable and correct since it leads to decision as to whether the process causing the difficulty can be arrested or its effects can be corrected. Furthermore, the appraisal of deficit leads to proper classification or "diagnosis."

2. A search for the cause is made. This is the "etiology" of the medical vocabulary.

3. The ordinary course of the disease or the ordinary effect of deficit is then considered in terms of "prognosis."

4. Treatment designed to control an active disease or to ameliorate the disability is finally considered.

On the whole, the doctor is discharging his most obvious responsibility when he has competently appraised and managed deficits. The problem is then frequently handed over to a new group who attempt to develop the remaining assets.

Efficient teamplay between doctors and teachers is possible even under these conditions, if it is possible to arrive at a valid residue by an agreed formula. For instance, it is quite possible to carry on education of a child whose right arm is completely disabled by infantile paralysis. The psychological integrity of the child and the efficiency of the remaining limbs can be assumed. The industrial effectiveness of the assets and liabilities can be appraised and no confusion exists.

The difficulties pile up rapidly, however, when the medical appraisal is

* Read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

either inadequate or is not easily translated into terms of remaining assets. The doctor must deliberately attempt to add a very difficult section to his formulation. He must, I think, try to define the remaining assets so that the psychological and physiological remainder will be understood by those who are responsible for education.

Fortunately the problem of infantile paralysis lends itself to accurate study. Essentially the disability is due to the subtraction of a certain number of units of motor function from a known total of identical units. The deficit can be calculated and the remainder obtained by the familiar process of subtraction. By development of remaining muscular tissue, by substitution of apparatus for lost fibers or by fixation of joints, a maximal efficiency can be reached. The fact that infantile paralysis is common and that the medical deficit is easily translated into terms of educational assets, leads, I think, to a feeling that the same process can be applied with equal effectiveness all along the line.

There is a second group, fortunately less common, where a disease, in the ordinary sense, is still active. Certain children have, for instance, tuberculosis of joints. Here the motor disability is only one factor. It is impossible to deal with the child on any basis which assumes that the balance-sheet is more than an expression of opinion concerning the immediate status. Obviously the responsibility of the physician is continuous and the teacher is unable to work out long-time plans with any security.

A third group, fortunately still smaller than the last, have remorselessly progressive disease. The child with progressive dystrophy, for example, has constantly decreasing assets. There is not confusion since again the conclusions of the doctor as to increasing deficits are easily understood.

The next group, which is relatively large, is much more difficult to manage. Injuries or disease of the brain, with consequent disturbance of motor control are not uncommon. Cerebral palsy is perhaps as useful a name as any for this group. In general, the cause is a diffuse abnormality of the brain due to various causes of which injury at birth is probably the major one. For obvious reasons it is desirable to ignore in the discussion two major groups—first, those whose intellectual equipment is not adapted to educational procedures, and second, those under continuous medical care because of advancing symptoms.

The children who are relevant suffer, not from isolated abolition of motor function, but from confusion of control of motor function. Obviously a mere process of subtraction will not give us a clean-cut picture, even of the motor deficit. The medical formula in terms of anatomical deficit is complicated. The appraisal of physiological disorder is also difficult. In addition there is almost always an intellectual irregularity or deficit. The duty of the doctor seems to me an arduous one. If endless confusion and frustration are to be avoided he must arrange his material so that his conclusions can be effectively used by parents and teachers. He does not discharge his responsibility until he has indicated the remaining physical and mental assets, suggested a type of training compatible with these assets, and discussed the probable ultimate level of efficiency.

I have no illusions about the difficulties of management of crippled children. Failure of the best known procedures is inevitable in certain cases, but the next step which is being taken in various places is to recognize that the doctors, instead of confining themselves to the appraisal and management of defect, must coöperate

with psychologists, psychiatrists, and teachers in formulating a conception of assets. If they succeed they can then coöperate in the planning of an educational routine which will lead toward an attainable goal.

Two equally confusing and dangerous attitudes are common: The ir-repressible optimist sees no limits to the spiritual or intellectual achievement of the crippled child; the almost certain result is frustration and disillusionment if remorseless limitations have been overlooked. The pessimist

who looks with pitiful despair on the poor broken children, is equally deplorable.

Doctors, teachers, and psychologists ought to be able to define liabilities and assets of individual children and to get away from generalizations which are inaccurate and misleading. Until such concerted efforts are carried out in all centers for the care of crippled children, we will have no reliable progress. Inspirational talks arouse interest, but furnish no solid basis for adequate educational planning.

Fatal Accidents in 1937

ONCE again, as the year draws to a close, we scan the national accident record. Once again the verdict is unsatisfactory. This is now clear, even though all the records are not in. Every indication, particularly the index of the National Safety Council, points to a toll of around 104,000 killed in accidents of one kind or another, the highest figure for any year with the single exception of 1936, when, according to the National Safety Council's estimate, the all-time high figure of 111,000 deaths was reached. As compared with this record figure, 1937

showed a recession by more than 6 per cent.

Accident fatalities in the home or in public places (exclusive of motor vehicle fatalities) apparently were lower in 1937 than in 1936. Motor vehicle and occupational accident fatalities, on the other hand, increased.

The ugliest feature of the accident situation was a rise of about 2,000 in the number of motor vehicle fatalities, bringing the total to the unheard of figure of 40,000 deaths in one year, a new high record.—*Statistical Bulletin*, Metropolitan Life Insurance Co., Dec., 1937.

Measurement of Sanitary Ventilation^{*†}

WILLIAM FIRTH WELLS AND MILDRED WEEKS WELLS

Laboratories for the Study of Air-borne Infection, University of Pennsylvania, Philadelphia, Pa.

ABILITY to modify man's environment is not confined to the enhancement of comfort, convenience, or even safety but extends to the prevention of disease and the promotion of health. By supplying pure water and pure food, the sanitary engineer has, in many communities, almost eliminated intestinal infection. Is it unreasonable to hope that, when air-borne infection is better understood, diseases conveyed through the respiratory tract may likewise be reduced through the provision of pure air supplies?

Experimental evidence has accumulated during the past few years which brings this possibility within the realm of the engineer.¹ It has been shown:

1. During coughing and sneezing, minute droplets containing microorganisms from infected surfaces may be ejected into the air.²

2. Most of these droplets are sufficiently small to evaporate before they can settle to the ground, leaving suspended in the air minute residues.³

3. These nuclei, in which the microorganisms remain viable for considerable periods, may drift in air currents as would particles of cigarette smoke.⁴

4. The air breathed commonly by the various persons congregated in a room or

other enclosed space can thereby transfer these organisms from one person to another and plant them upon the susceptible tissues of the respiratory tract.¹

The engineer may, therefore, proceed upon the assumption that drifting particles arising from common occupancy of enclosed spaces constitute a hygienic hazard, which may be reduced through the elimination of the microorganisms thus suspended in air. Where individual supplies of air can be furnished to each person, the problem of air-borne infection disappears. Blackfan and Yaglou⁵ report spectacular reduction in acute and chronic infection of premature infants, chiefly respiratory, by the installation of a separate air-conditioned supply to wards for premature infants. The Chapple incubator⁶ by providing an individual supply of pure outside air to each infant attains this theoretical ideal, for even the nurse is excluded from the child's atmosphere. Whether the principle of the individual air supply can be profitably prolonged beyond the premature into the normal life span is a problem of hygiene as well as engineering. The practicability of a cabinet cubicle for infant care in nurseries is now being studied by Dr. Chapple in the Laboratory of Air Hygiene at the Children's Hospital, Philadelphia.

In general, however, the engineer must provide for common occupancy of enclosed spaces. The magnitude

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

† This study is supported by a grant from the Commonwealth Fund to the University of Pennsylvania for investigations on air-borne infection with the laboratories in the Department of Bacteriology, the Children's Hospital, and the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis.

of this hazard depends upon the degree of confinement of the air common to many persons, or rather upon the concentration of the contaminating nuclei, which varies directly with the number of persons occupying a given volume of air (and their specific infectivity), and inversely with the dilution either with pure air from without or with any other equivalent means of elimination of the microorganisms, such as precipitation, filtration, washing, physical or chemical disinfection. As Colvin has said,

The fundamental factors in prevention or control of droplet infection become evident. Dilution of the droplets by air space or change of air provide the barrier, *i.e.*, proper space for each one, especially in sleeping, and proper ventilation.⁷

Sanitary ventilation may, therefore, be defined as the rate at which microorganisms are vented; or as the proportional air replacement which would remove the equivalent number of micro-

organisms eliminated by any other means.

METHODS OF MEASURE OF EQUIVALENT VENTILATION

With the modern technic of sanitary air analysis,⁸ the equivalent air replacement can be simply determined. A diluted culture of the test organism is thrown into the air by an atomizer (Figure I) which may be designated the infector. Following the instantaneous evaporation of the droplets, the contained bacteria remain suspended in the air like an invisible smoke. The bacterial concentration may be determined by the air centrifuge,⁹ which represents a mechanical infectee. The specific technic is contingent upon the dimensions involved.

B. coli is a convenient test organism: it is harmless; it is easy to culture, and we have in eosin-methylene blue agar a selective medium in which *B. coli* grows readily but which is in-

FIGURE I—Atomizer adapted from special assembly of humidifier by William Feldermann, American Gas Accumulator Co., Elizabeth, N. J.

hibitive to other organisms in the air (in these tests, contaminants); on this medium the colonies are readily counted¹⁰; it grows singly; it is not a normal inhabitant of the air, and one can be sure that the organisms recovered by the centrifuge were put there by the atomizer.

It becomes possible, therefore, by a suitable technic to measure directly the degree to which an infector at any point in a confined space infects an infectee at any other point under given conditions of ventilation. By comparing these measurements under varying conditions of ventilation we are provided with a quantitative instrument for measuring sanitary ventilation as defined above.

Two general methods are described which make it possible to study specifically the conditions which facilitate or impede the passage of infection from infector to infectee and to determine the efficacy of any means for preventing or reducing such passage of microorganisms. These measurements may be compared to the effect produced by removing from the confined space a given proportion of the volume of air in a chosen unit of time, the removal rate giving a unit of equivalent ventilation. Replacement of the confined air by outside air or air from other parts of the building by natural or artificial means, or removal or destruction of microorganisms within the air, all can be expressed in terms of equivalent ventilation.

I. Method of the Die-away—The simplest method for determining the ventilation rate is to build up within a room a desired bacterial concentration by atomizing a diluted liquid culture of the test organism; the atomizer is then turned off and consecutive samples of the air are taken.⁸ Since with uniform ventilation the number of organisms removed in a small unit of time is proportional to the number present,

that is:

$$dN = -KNdt$$

it follows that

$$\log_e \frac{N}{N_0} = -Kt \text{ and } N = N_0 e^{-Kt}$$

The difference between the logarithms of two counts divided by the elapsed time between the two samples gives the value K . The value K as thus determined by using natural logarithms becomes the rate at which microorganisms are being vented and therefore a measure of sanitary ventilation. If we express time in minutes K then represents the proportional air replacement per minute which would vent an equal number of organisms and therefore becomes a unit of equivalent ventilation. Multiplied by 60, the equivalent turnovers per hour as understood by the ventilating engineer can be ascertained.

Since K is more conveniently calculated by common logarithms, the K so determined must be multiplied by 2.3 to obtain the equivalent ventilation as given above, or the K is multiplied by 138 (2.3×60) to obtain the turnovers per hour. The working rule for obtaining equivalent sanitary ventilation becomes: *the number of over-turns per hour is equal to 138 times the difference in the logarithms of two counts divided by the elapsed time in minutes between the two counts.*

II. Method of Equilibrium—If an infector contributes bacteria to the air at a uniform and constant rate, the number within the space will increase until the number removed will equal the number added in a unit of time. If the number removed, as given by the *method of the die-away*, is a constant proportion of the number present, it follows that when the rate of removal multiplied by the number present equals the rate of addition, equilibrium will have been reached. The concen-

Test room: 20' x 20' x 12'; 3 windows on one side, 1 on another; 3 doors on other two sides—all closed

Atomizer placed near center of 3 window side, 8' from floor; heating radiators beneath created an up-draft; ordinary home electric fan blowing toward atomizer created a cross-draft

Centrifuge at opposite side of room from atomizer, 3' from floor

* Note: Same lamp without Corex D filter gave in another test 537 overturns per hour

tration in the room when equilibrium is reached, therefore, is equal to C/K where C is the addition rate and K is the removal rate (given by the method of die-away).

If a ventilating factor is changed, then the new equilibrium will adjust itself in accordance with this equation, and by dividing the number per unit volume obtained under the two conditions of equilibrium, the addition factor cancels and the removal rates will vary inversely with the equilibria reached. If any removal rate has been determined by the die-away curve, removal rates obtained with other ventilating factors may be readily compared by the ratios between the equilibria obtained by test.

For example, under three consecutive conditions of ventilation we obtain equilibria C/K , C/K_1 , and C/K_2 from which K_1/K and K_2/K can be obtained by division. These ratios multiplied by K , as determined by the method of the die-away, give the values of K_1 and K_2 .

(In the sample test, the elapsed time between samples is 6 minutes. The counts are conveniently computed into logarithms as given in the record. The difference between logs X and XI , or XI and XII , divided by 6 gives K . Subtracting from the log of C/K , log C/K_1 and log C/K_2 gives log K_1/K and log K_2/K , from which K_1/K and K_2/K are obtained. Multiplying by K , as determined from the die-away, gives K_1 and K_2 . Multiplying K , K_1 , and K_2 by 133 gives overturns per hour.)

The time required for an equilibrium to be reached is theoretically infinite but under practical conditions can usually be obtained within a reasonable period. It is possible.

however, to express the number obtaining at any time after the commencement of the addition by the formula:

$$P = \frac{C}{K} (1 - e^{-Kt})$$

which reduces at zero time to zero and approaches an asymptote C/K as the time is prolonged to infinity. It will be further seen that the greater the value of K , the more rapidly does the number approach this asymptote.

It may be inconvenient to solve for the value of C/K by determining the shape of this curve, and yet the time required to approach the practical equilibrium may be longer than desired in making a test. The accurate determination of three points at equal intervals, as by taking three consecutive samples, permits the computation of C/K . Bacteriologic analyses ordinarily are not sufficiently precise to locate the asymptote accurately, but this relationship assists in the graphic location within the accuracy demanded in practical tests. It is characteristic of this curve, whether increasing or decreasing, that the product of the extremes minus the square of the mean divided by the sum of the extremes minus twice the mean gives the asymptote C/K . Thus if x , y and z are tube counts of three consecutive air samples taken with equal intervals between (see sample test), then:

$$\frac{xz - y^2}{x + z - 2y} = \frac{C}{K}$$

(In the example, counts I, II and III can be substituted for x , y and z , and so also can counts VII, VIII and IX. When, however, the formula is applied to counts IV, V and VI, the deviation of the count of one tube destroys the natural sequence for the solution is found by inspection to be unreasonable. The equilibrium is therefore assumed to be reached with count VI, although a more experienced judgment might apply a graphic correction.)

Because of individual variation in death rate of organisms in the same culture, and other technical factors, the technic must be standardized as far as possible to assure closely comparable results. The dimensions given by this typical test have been found by practical experience to yield reproducible results.

The irradiation of recirculated air constitutes a simple case of bacterial ventilation by means of ultra-violet light. If the efficiency of such ventilation is determined by samples taken within the recirculation system before and after irradiation, the fraction of the bacteria removed represents the fraction of the recirculated air which may be assumed to replace by pure air the contaminated air of the room. Equivalent sanitary ventilation is thus limited by the rate of recirculation. If only 10 per cent of the air is recirculated per minute, the highest equivalent ventilation by any system of purification or by supplying entirely fresh outside air would be 6 turnovers per hour. Compared with the sanitary ventilation obtainable by treatment of the whole volume of air of occupied spaces (discussed under B and C and D) this fractional method of replacement of room air with pure or purified air by mechanical means, hitherto available to the ventilating engineer, is completely out of range. (In the sample test (Table I) a ventilating equivalent of 116 turnovers per hour was easily obtained, and other routine tests could be selected showing several thousand turnovers per hour.)

In special cases, such as railroad cars,* the rate of recirculation may be as high as 20 turnovers per hour, and therefore the irradiation of the recirculated air provides a feasible method of sanitary ventilation, especially since the occupancy load is high and usable space is greatly restricted.

B. Direct Irradiation of Room Air—
In the previous case the change in the room air is given by a percentage reduction of a percentage recirculation.

BACTERIAL VENTILATION BY ULTRA-VIOLET IRRADIATION

A. Irradiation of Recirculated Air—

* A study of the purification by ultra-violet radiation of the recirculated air of railroad cars is being conducted in collaboration with S. M. Anderson, Research Engineer of the B. F. Sturtevant Co., Hyde Park, Mass.

Direct irradiation of the whole room is far more effective in the special instances where the eyes of the occupants can be protected. An operating room furnishes a special instance of such irradiation, since the discipline maintained permits responsible protective measures. Here reflectors containing the burners, installed in the angles where ceiling and walls meet provide general irradiation of the major portion of air in the operating room, and

throw a broad beam of ultra-violet light onto the operating table.*

Such an installation may be tested by placing the infectee in the center of the room at the level of the operating table (this being the critical point of protection); by continuously infecting the air with an infector placed successively in each corner of the room;

* This type of installation has been under test by Dr. Richard Overholt, Department of Thoracic Surgery, New England Deaconess Hospital, Boston, Mass., for about a year.

FIGURE II—Photographic projections of actual centrifuge tubes obtained in routine test on operating room. Tubes represent 10 minute samples with 1 minute interval between. Tubes I (omitted from picture), II and III represent build-up of bacterial concentration without lights, with infector in each of three corners successively. Lights turned on at end of each 3rd sample and off at end of each 5th sample before moving infector to another corner of room. Infector ran continuously throughout test.

and testing each location of the infector with the lights on and the lights off. The ratio of the equilibrium counts obtained with the lights off and the lights on then gives a measure from which the sanitary ventilation attributable to the lights can be calculated. Their power actually determined under such circumstances by the method of equilibrium, appears fantastic when converted into equivalent ventilation units, and can be better illustrated than computed (Figure II).

C. Partial Irradiation — Direct irradiation applies to special cases. The general problem of the sanitary air control of schools, institutions, etc., can be solved by partial irradiation, where the space without the eye zone is directly irradiated. The irradiation of the upper air of a room may be regarded as equivalent to removing the ceiling or ventilating upward instead of by windows if the air circulation could then be comparable to that in a room. The disinfection of the air in the unirradiated zone depends upon air movement through the irradiated space, as well as upon the spatial distribution of the radiation.

Careful design, operation, and regulation, though necessary in all sanitary light installations,* are of particular importance with partial irradiation because efficiency rests primarily upon the relationships established between the irradiated and unirradiated portions of the room. The integrated product of intensity and time of exposure for all the living organisms within the space which determines the number killed,² mathematically predictable in ideal geometric configurations,¹ must be bacteriologically determined in the practical solution of partial irradiation. The routine test illustrates how de-

terminations between different points with lights on and lights off can be converted into equivalent ventilation.

Until opportunities to test buildings specially designed for irradiation become available, experience gained with empirical installations must serve to establish design principles as well as guide in effective regulation.†

D. Light Barriers — Ultra-violet screens or barriers constitute another special application. The air of cubicles‡ separated from the surrounding air of a ward by ultra-violet light screens can be tested either by placing the infector within and the infectee without (representing the protection offered the surrounding ward from a person ill within the cubicle), or by placing the infector without the cubicle and the infectee within (representing the protection offered a person within the cubicle from the surrounding ward). In each instance the bacterial tightness of the light-enclosed space is determined by the method of equilibrium.

In an isolation hospital, where a light barrier is thrown across a corridor to separate two contagious diseases,** the efficiency or bactericidal power of this barrier may be determined directly under the actual ventilating conditions in the corridor. The infector is placed on one side of the barrier and the infectee on the other, samples being taken with the lights on and off. The infector and infectee are then reversed and the test duplicated. Tests made by the method

† Such experimental installations are now being tested at the Children's Hospital, Philadelphia, Pa.; the Germantown Friends' School, Germantown, Pa.; and the Marlboro State Hospital, Marlboro, N. J.

‡ Tests are now being conducted in the Laboratory of Air-borne Infection at the Henry Phipps Institute, Philadelphia, upon cubicle design, in collaboration with C. A. Erikson, of the firm of Schmidt, Garden & Erikson, consulting architect for the Cradle Society, Evanston, Ill.

** Dr. Charles F. McKhann first applied this principle to a corridor in the Isolation Unit of the Children's Hospital, Boston, Mass., and he has observed the results for about 1 year.

* Studies on air disinfection are being conducted at the Laboratory of Sanitary Ventilation, Department of Bacteriology, University of Pennsylvania Medical School.

of equilibrium have shown that light screens can be made practically impervious to bacteria suspended in droplet nuclei and carried by ordinary ventilating currents.

SUMMARY

These examples serve to illustrate the manner in which the essential technic can be adapted to special problems. In each instance the measure of equivalent ventilation between any two points can be expressed in terms of the proportional pure air replacement throughout the whole room which would bring about the same reduction in the infection transferred from one to the other point.

CONCLUSIONS

In attempting to define bacterial ventilation in specific terms, the engineer is entitled to assume that the value of C , as indicative of the number of persons per given volume of air space represents a degree of potential infection, and to regard the value of K as indicative of the rate of reduction in this potential hazard resulting from the instruments of ventilation, and the ratio C/K an index of the relative hazard in one room as compared with another. Whether or not such an index can be correlated with epidemiological experience remains a major problem of sanitary science. Installations of ultra-violet lamps have been set up

under competent and rigid medical control in order to determine the value of such measures under specific conditions, and until such conclusions are available to the engineer, he can only be guided by the bacteriological evidence. When indices of sanitary ventilation are correlated with the epidemiological data on a sufficiently large scale, the results should guide the engineer to the proper design of ventilating instruments. This may lead to a realization of our present hope that if the sanitary quality of air is controlled, reduction of respiratory disease will be accomplished.

INTRODUCTORY STATEMENT

SHELTER is one of the three fundamental needs of human existence. No housing program can be sound unless the shelter it provides is healthful. It was this latter consideration which led the American Public Health Association to organize a Committee on the Hygiene of Housing, to serve also as the organ of coöperation for the United States with the Housing Commission of the Health Organization of the League of Nations.

In beginning the work of this committee it has seemed essential to formulate the basic health needs which housing should subserve. This report is a preliminary attempt at such a formulation.

This report consists of 30 basic Principles, with Specific Requirements and suggested Methods of Attainment for each. The Principles and Specific Requirements are believed to be fundamental minima required for the promotion of physical, mental, and social health, essential in low cost as well as high cost housing, on the farm as well as in the city tenement. Under Methods of Attainment are suggested the more important means by which these objectives can be achieved, without excluding alternative means of attaining the same ends, and without attempting exhaustive treatment of the many technical points which are covered elsewhere in the literature of housing and construction methods.

In view of the present status of the

housing program in the United States, particular emphasis has been placed, in drafting these Methods of Attainment, on the needs of new urban construction. The Principles and Specific Requirements, however, are equally valid as a guide for new rural construction or for the appraisal of older housing whether rural or urban, inasmuch as they are based on fundamental biological requirements.

Many of the objectives stated involve problems of management as well as of planning and construction. This must be the case if we are concerned with results achieved, and not merely with requirements on paper. Under the hopeful policy envisaged by the new public housing program—that of continuing management responsibility by local housing authorities—it should be possible to approve given types of housing facilities only for stated conditions of use and occupancy, just as elevators have long been licensed to carry only a certain number of persons, or warehouses a given floor-load.

The report here presented is a preliminary one. In the text are noted points which require further investigation. The committee is conducting research on certain of these points and will follow the findings of other agencies in the field, toward the end that the present report may be revised and amplified in the light of accumulating knowledge.

C.-E. A. WINSLOW, DR.P.H., *Chairman,*
ALLAN A. TWICHELL, *Technical Secretary,*
Committee on the Hygiene of Housing

SECTION A

FUNDAMENTAL PHYSIOLOGICAL NEEDS

Principle 1. Maintenance of a thermal environment which will avoid undue heat loss from the human body

a. *Specific Requirements*—The chief variables controlling heat loss from the human body in a dwelling (since neither air movement nor humidity is likely to be considerable) are air temperature and the mean radiant temperature of surrounding surfaces (walls, windows, radiators, human bodies, open fires). The combined effect of air temperature and mean radiant (or wall) temperature is defined as "operative temperature." For ordinary dwelling conditions, operative temperature may be taken as approximately the mean between air temperature and wall temperature. For the normally vigorous person, normally clothed, and at rest, an operative temperature of 65° F. is the minimum. In all regularly occupied rooms this temperature should be provided at knee-height, 18 inches, in order to prevent chilling of the legs and feet. Air temperature may be increased or decreased in order to compensate for deviations of mean radiant temperature above or below air temperature.

In rooms occupied by persons of sub-normal vitality, operative temperatures must be higher than 65° F. Since dwellings are designed for occupancy by old people and children, the heating system should be able to provide an operative temperature of 70° F. at knee-height under ordinary winter conditions. Such a temperature is, however, unduly high for the normal adult and should not ordinarily be maintained.

Considerable vertical differentials of air temperatures are highly undesirable, since they involve waste of fuel (from increased heat loss through the upper areas of the room), and since they not only produce local chilling of the lower extremities, but also increase convection currents. From this standpoint radiant heating has special advantages, since it maintains a very low floor-to-ceiling differential. With ideal radiant heating, knee-height temperatures and 5 foot temperatures would be almost identical. With ordinary free-standing radiators a knee-height temperature of 70° F. would ordinarily imply a 5 foot temperature of 76° and a ceiling temperature of 80° F.

b. *Methods of Attainment*—The practical measures to be taken in housing design to meet these needs must, of course, depend upon climate, but it should be possible to reach the limiting temperature of 70° F. at knee-height under ordinary minimum winter conditions for the locality concerned. The usual figure for outside temperature taken by engineers as a basis for their computations is 15° F. above the lowest recorded temperature for a 10 year period.

The heating equipment provided will also, of course, be closely related to the insulation of the building. Superior types of construction, weather-stripping and the use of double windows, and the use of insulating materials in ceilings and walls may, in cold climates, reduce heating costs by 50 per cent or more. Such insulating capacity should, therefore, be provided as is justified by fuel economy balanced against ad-

ditional construction costs. The balancing of these factors is a problem deserving special study.

For low-rent housing in one- or two-story dwellings, the circulating heater type of stove will generally prove the most economical heating equipment. For apartments, and perhaps for large groups of one- and two-family houses, steam heat from a central plant should prove equally economical. Central heating cannot wisely be replaced by stoves in the multi-story dwelling because of fire hazard and the problems of fuel storage and ash disposal.

For more expensive installations, hot water heating has certain advantages. Indirect heating by hot air may also be employed. Where indirect heating involves considerable air change, permissible lower limits of temperature may have to be raised (to balance increased rates of convection loss from the body).

The possibilities of low temperature radiant heating by steam or hot water or, where power rates are low, by electricity, should be given careful consideration.

Flooring materials of high heat conducting value should be avoided, particularly where children may play upon the floor. Loss of body heat by radiation to windows may be controlled by curtains. Excessive dampness combined with low temperature will increase heat loss from the body and may cause chilling, but this condition is not common in the United States.

It should be particularly emphasized that bedrooms need not always be maintained at 65° F. when unoccupied, or when occupied for sleeping.

If intermittent radiant heating is available the bathroom may also be maintained at a lower temperature. Additional local heating units, on the other hand, may be necessary in rooms occupied by persons of subnormal vitality.

Principle 2. Maintenance of a thermal environment which will permit adequate heat loss from the human body

a. *Specific Requirements*—The factors involved here are, again, air temperature, mean radiant temperature of the surrounding surfaces, relative humidity, and air movement. In cold weather, air movement and relative humidity inside the dwelling will normally be low, and the determining factor will be operative temperature, which should not exceed 75° F. within the zone of occupancy. In warm weather, humidity will decrease the limit of tolerance, and air movement will increase it. The human body is of course acclimated to higher temperatures in summer than in winter.

It is particularly important that cool moving air be made available in sleeping-rooms, since the impact of cool air is of great value in promoting healthful sleep.

b. *Methods of Attainment*—In the winter season, it should be possible to prevent overheating by proper manipulation of heat sources with a minimum use of windows. In the case of steam heated dwellings, such control is frequently difficult; both effective operation of central heating plants and a maximum of individual control of heat supply to each room are essential for satisfactory results.

In summer, air cooling and air dehumidification are valuable adjuncts to comfort, but are beyond the present economic limits of the low-rent dwelling. In the free-standing house, the installation of an exhaust fan at the top of the house to draw in cool night air through windows is also an extremely helpful, but somewhat costly procedure. In the low-rent home we must insist on through- or cross-ventilation, and it would seem not unreasonable to include in the equipment of such a home at least one electric fan

for cooling, in regions where summer heat is considerable.

Both warming in winter and cooling in summer are materially aided by suitable orientation of the dwelling as discussed in a subsequent paragraph.

Principle 3. Provision of an atmosphere of reasonable chemical purity

a. *Specific Requirements*—The important atmospheric impurities present in the home under ordinary conditions are those contributed by cooking, by various heat sources, and those derived from the human body. (Hazards from heating sources and those associated with special toxic gases will be considered in a later section.)

The odors given off from the body have been proved to exert a definitely harmful influence upon appetite and therefore upon health. With persons of reasonable cleanliness the dilution of these odors will require an air change of 10 cu. ft. per person per minute.

b. *Methods of Attainment*—Such an air change as this, with any ordinary type of construction, will be automatically attained in cold weather by normal leakage through walls and ceilings of ordinary porosity and around doors and windows, provided the cubic space per occupant is 400 cu. ft. in any occupied room, and that the normal ratio of fenestration is supplied. The necessary air change can be secured in summer by the opening of windows. Since this minimum of 400 cu. ft. is demanded by other fundamental needs to be discussed in later paragraphs, no other provision for air change need ordinarily be made in the low-rent dwelling. If the other fundamental needs could be met, and if dependable artificial ventilation were provided, a lesser air space might be permissible.

It should be noted that this standard of 400 cu. ft. applies to any occupied room. Where separate rooms are used

for living and sleeping, the total for the living portions of the dwelling must be 800 cu. ft. per person. Where the same room is used for both living and sleeping, the value should be increased to 500 cu. ft. to allow for necessary furniture.

Ceiling height may, in general, be determined by cubic space requirements and by necessary window heights.

Principle 4. Provision of adequate daylight illumination and avoidance of undue daylight glare

a. *Specific Requirements*—In order to avoid danger of eye strain and facilitate cleanliness, the minimum light value available for any occupied space relying upon natural illumination should be 6 foot candles, on a horizontal plane 30 in. above the floor.

b. *Methods of Attainment*—With unobstructed exposure to the sky, the minimum illumination defined above will be obtained in clear weather and up to a reasonable time before sunset (in the latitude of Washington, D. C.) with an area of window glass equal to 15 per cent of the floor space of a room (provided that walls and ceiling are light in color). In other latitudes the necessary window area may be greater or less. Findings of the U. S. Public Health Service on this point are being assembled by the committee.

With buildings so closely grouped as materially to obstruct sky shine, daylight illumination will be seriously hampered. This subject requires further study. At present, it seems reasonable to require at least a 45° sky angle at the lowest window sill, which implies that the width of intervening street and court space should approximate at least the height of opposite buildings. Porches should not be so placed as to obstruct the entrance of light.

All rooms, including bathrooms, should have at least one window open-

ing to the outer air. Daylight illumination should be provided for public halls and stairs, except perhaps in elevator apartments with adequate janitor service.

It is of advantage to have the tops of windows as near to the ceiling as possible, to give the greatest sky angle in all parts of the room and thus to secure the greatest lighting effectiveness. Inside walls of a good reflecting value are essential factors in obtaining the desired result. Glossy paint should be avoided on account of glare; ceilings should be matt white.

For control of glare, suitable window shades are essential; those of the Venetian blind type, although costly, are desirable, since they protect from glare while reflecting light to the inner part of the room. Windows extending below 30 in. from the floor tend to cause glare and obstruct furniture placement without materially increasing the general illumination.

It should be noted that good natural lighting is often interfered with by internal obstructions, such as draperies and furniture. It would be of advantage, where available light is near the desirable limit, so to place curtain rods that draperies may be hung adjacent to, rather than over, the windows.

Principle 5. Provision for admission of direct sunlight

a. *Specific Requirements*—No definite quantitative limits can be set; but it is clearly desirable for all dwellings, and essential for those occupied by persons who are housebound, that direct sunlight should enter at some places and hours, even in winter. Sunlight, particularly through its ultra-violet components, provides valuable physiological stimulation.

b. *Methods of Attainment* — Insolation in a given room depends on sky angle as related to that area of the sky

occupied by the sun's orbit at a given season. It will be materially influenced by orientation, by buildings or projections so located as to cut off morning and evening sun, and by the placement of windows. In the northern latitudes of the United States, a generally southerly orientation of rooms for daytime occupancy is most desirable since it gives a maximum of sunlight in winter.

Under the meteorological conditions which characterize New York City, an orientation of living-rooms 25° west of south has been found to yield a maximum of effective sunlight in winter and a minimum in summer. This relation is important in temperature control and heating economy as well as in penetration of sunlight; it should be studied for other areas.

Casement windows, because of their larger clear opening, are more desirable than double-hung windows from the standpoint of admitting the ultra-violet rays of sunlight; but they permit undue heat loss if not tightly fitted.

Principle 6. Provision of adequate artificial illumination and avoidance of glare

a. *Specific Requirements* — Artificial illumination of 6 foot candles should be generally available in all occupied rooms, with at least 10 foot candles at certain points for reading, study, or sewing. Illumination of at least 1 foot candle should be provided on stairs and in passageways to minimize danger of accidents. Glare effects should be avoided in the design and location of fixtures.

b. *Methods of Attainment* — The maintenance of the illumination specified above, and the avoidance of accident hazards due to oil lamps, can only be attained by the use of electricity. Electric lighting should be considered a minimum requirement for the healthful American home.

There should preferably be a central outlet in the ceiling of each room, with two convenience outlets in the living-room and one in each of the other rooms. In the kitchen, shadows on the sink and work table should be avoided, if necessary by installing a second fixture. In the bathroom the central fixture may be replaced by lighting adjacent to the mirror.

Sleeping-rooms should be protected from artificial external light sources such as street lights and electric signs.

Principle 7. Protection against excessive noise

a. *Specific Requirements*—Excessive noise, a factor much neglected in the United States, is of serious moment in so far as it causes nerve strain and interferes with sleep and other physiological processes. It should be possible to exclude noises from outside the dwelling unit to such a degree that within that unit the noise level shall not exceed 50 decibels; and a level as low as 30 decibels should be attainable in rooms used for study or sleeping. These standards are based on European practice and call for further examination under American conditions (including the prevalence of radios and automobiles) and under American habituations.

b. *Methods of Attainment*—The solution of this problem depends, first of all, on the control of external sources of noise, which involves the avoidance of dwelling sites with exposure to special sources of noise (factories, highways, railroads, athletic fields, and the like), and the control of motor horns and other sources of vehicular noise.

With a given environment it calls for such construction as will reduce the noise from external sources to the levels stated above.

For control of noises transmitted by air within a building, party walls

should effect a reduction of 50 decibels (approximately the result produced by an 8 inch brick wall). For control of structure-borne noises knowledge is inadequate, but the Sub-Committee on Noise of the Housing Commission of the League of Nations recommends that floors should be designed with a noise-insulating value at least 15 decibels superior to that of a bare concrete floor. (The concrete floor would probably insulate adequately against air-borne sounds.)

Further study on these points is being made by this committee.

Principle 8. Provision of adequate space for exercise and for the play of children

a. *Specific Requirements* — Opportunities for physical exercise and recreation, for both children and adults, are essential to a sense of organic well-being and the enjoyment of mental health. While these ends may be considered as primarily psychological in nature, they are attained by physiological processes and may therefore be considered under the present category. The attainment of the purposes indicated calls for adequate floor space within the dwelling and, under urban conditions, for outside space which has been defined in terms of from 3 to 5 acres of park and play spaces per 1,000 persons, in addition to more distant regional park areas. The National Park Service suggests 10 acres (including parks adjoining a city).

b. *Methods of Attainment*—For city dwellers it has been suggested that the recreation area should include a playground within such distance as to be practically accessible, and an athletic field within half a mile of each home for the use of adolescents. It is desirable that play space for young children (separated from adolescents) should be available within sight of the dwelling.

This subject of standards for recrea-

tion space is receiving further study by this committee.

It should be emphasized that provision of recreation facilities is by no means necessarily a function of housing authorities, except in large urban projects where community morale may affect the success of the project. Such facilities are logically chargeable to the community as a whole, rather than to

a specific housing project. Yet it is clearly the responsibility of the housing authorities to be certain that such facilities are, or will be, available before approving a housing scheme. In large urban developments the management may make provision for trained leaders of club and recreational activities if such service is not otherwise available.

SECTION B

FUNDAMENTAL PSYCHOLOGICAL NEEDS

Principle 9. Provision of adequate privacy for the individual

a. *Specific Requirements*—The essential concept of a home involves the possibility of that isolation from the world which every human being sometimes craves and needs. Especially in cities, the home is a needed refuge from the noise and tension of the street and marketplace. The same principle applies within the home itself. When the dwelling unit is crowded, frequent personal contacts may be the cause of nervous irritation, as detrimental to mental health as is the more obvious influence of contact infection upon physical health. "A room of one's own" is the ideal in this respect; but we can at least insist on a room shared with not more than one other person as an essential minimum. Such a room should be occupied only by persons of the same sex except for married couples and young children. The age at which separation of sexes should occur is fixed by law in England at 10 years, but some American authorities would place the figure 2 years lower. Sleeping-rooms of children above the age of 2 years, according to psychiatric opinion, should be separate from those of parents.

Furthermore, fundamental habits of decency demand that toilets, bathrooms, and bedrooms should be acces-

sible from halls or living-rooms without passing through other bedrooms or bathrooms.

Dwellings should be so spaced on their sites, and their windows so located, as to limit direct vision from one dwelling into the bedrooms of another.

b. *Methods of Attainment*—The objectives stated can be attained by various types of design, but they imply in practice at least the standards enforced under the current English legislation on overcrowding. Under this legislation, not more than 2 persons may occupy a sleeping-room. Two rooms are required for 3 persons, 3 rooms for 5 persons, 4 rooms for $7\frac{1}{2}$ persons, and so on. Bathrooms and sculleries are not counted as rooms. For the purpose of governing occupancy, infants under 1 year of age are not counted, and children between 1 year and 10 years are counted as half-persons.

It is desirable to provide sleeping space apart from the living-room, but when this cannot be done, the living-room must be provided with reasonable privacy, as outlined above.

Overcrowding cannot be prevented either by proper physical planning alone or by good planning plus care in the initial selection of tenants. It is also necessary that continuing super-

vision be exercised and that adjustments to changing family needs be made by management authorities. Limitation of boarders, control of sub-leasing, intelligent adjustment of rent schedules to family size and income, sympathetic handling of transfers or other problems due to changing family size or income are all involved in maintaining desirable conditions of privacy.

Principle 10. Provision of opportunities for normal family life

a. *Specific Requirements*—Privacy is one element in normal family life; but sociability is another, which is psychologically and socially quite as important. Opportunity for adolescent youth to meet persons of the opposite sex under wholesome conditions should be provided. To meet these needs a common living-room which can be occupied by all members of the family, plus reasonable space elsewhere for withdrawal during periods of entertainment, would seem essential. It is important for the establishment of friendships and the striking of family roots in the chosen community that continuous residence in that community should be possible through all the normal changes in family size and make-up; such continuity is intimately related to the provision of living-units adapted to families of various sizes. Furthermore, the entertainment and overnight accommodation of guests and relatives, which is as fundamental a family need in modern apartment life as in the tents of the Arabs, should be given consideration.

b. *Methods of Attainment*—A living-room providing 400 cu. ft. of space for each member of the family would seem a desirable ideal. In multiple-dwellings the needs for extra-familial social life can be met to a considerable degree by club-rooms and common rooms for a group of dwellings.

The continuance of the family in the community of its choice will be greatly fostered by the provision in every housing project of living units sufficiently varied in size to provide accommodations during the whole cycle of family development, from the phase of child rearing and gradually increasing family size, on to the period when parents whose grown children have set up their own homes will normally live by themselves. Related problems which must be solved by the planner are those of the non-typical household, such as the group of employed adults unrelated to one another and possibly desiring more than normal privacy, or the normal family plus grandparents or with an invalid member—in which cases unusual quiet or special access to the sun may be required. It is obvious that no advance provision can be made for each of these contingencies exactly as it will occur; the plea, however, can be made that the designers of housing visualize as fully as they can the varied uses of family life to which their buildings will be put, and that they provide all reasonable variety in plan arrangements. The housing needs of a population are not met by devising standard 3 and 4 and 6 room unit plans and repeating them endlessly without variation simply because they are efficient users of space and have an economical relation to plumbing stacks and stairs.

In this connection it is worthy of note that a responsible group of housing managers have recently cited as their greatest difficulty that of reconciling the living units they have to offer with the living needs of the families who apply to them for space. The conclusion seems warranted that these fundamental needs of family life have been seriously neglected in much recent American housing.

The temporary accommodation of guests and relatives is a difficult problem in the compact type of living unit

which characterizes most large-scale housing developments. In at least one recent American project it has been necessary to solve this problem by the conversion of an ordinary dwelling into semi-hotel facilities for week-end visitors and other temporary residents. It should be possible in certain large-scale housing projects to experiment with the provision of a few guest rooms serviced by the central management, and to determine in practice both the benefits and the problems attendant on providing such overflow facilities for normal family life.

Principle 11. Provision of opportunities for normal community life

a. *Specific Requirements* — In order to promote the psychological and social values which result from participation in normal community life, the home should be located in a community which contains or has easy access to the basic institutions of culture and commerce, and from which the major centers of employment can be reached without undue expense or loss of time and energy in travel.

Among the community facilities which should be made conveniently accessible to the home, the most important are: schools, churches, facilities for necessary local shopping and entertainment, libraries, and medical service. (Facilities for physical recreation have been discussed above.)

A vital community life should be fostered in housing developments by supplying, as a part of any new physical plant, the basic neighborhood facilities which are lacking, and by management policies which will encourage spontaneous community organization.

b. *Methods of Attainment* — This principle involves town and community planning and housing management as well as housing design in its narrower sense. It is, however, directly

related to the choice of sites for housing projects and the plans for their subsequent development.

The school and the workplace are vital elements in the community background of the home; they should be within reach without undue expenditure of time, energy, or money. Location of the school beyond a walking distance for the child may restrict his participation in normal and desirable extra-curricular activities. If adults are required to spend more than an hour a day in going to and from work, they may be subjected to considerable nervous and physical strain, and the time and energy available to them for recreation or participation in neighborhood activities may be materially curtailed. Suitability of location is obviously related to transportation facilities and to the family carfare budget, so that no definite standards can be set; yet the point is often of controlling importance in the selection of sites for housing development.

The provision, as an integral part of new housing developments, of community work-shops and of health centers or clinics which function under the existing local public health service appears to offer sound possibilities which have been little explored.

Although the attitudes of local governments and housing management toward the autonomous community life of housing projects should be sympathetic, great care should be taken to avoid freezing the lines of social cleavage that may so easily form around the project dwellers as a privileged group in the community. Management authorities should be alert both to encourage natural neighborhood groupings and to take advantage of normal social services existing in the area.

It should be noted that many recent housing projects not only meet the basic needs cited above but provide important opportunities for economic

coöperation and a sense of community responsibility far greater than is ordinarily attained in either urban or rural life. It seems possible that in this regard our housing program is making a substantial contribution to the most vital of all American political needs—the consciousness of and participation in the common tasks of community living.

Principle 12. Provision of facilities which make possible the performance of the tasks of the household without undue physical and mental fatigue

a. *Specific Requirements*—This principle involves avoidance both of physiological and psychological factors contributing to fatigue. The home is not merely a dwelling; for the housewife it is a work-place as well. Recent studies show that some 60 person-hours of home-making activities per week are required in the average home. The principles of sound industrial hygiene demand directness of circulation and good facilities for storage, cooking, laundering, and refuse disposal. Cleansing, which is also important in this connection, is discussed in a subsequent paragraph.

b. *Methods of Attainment*—In order to minimize fatigue from needless walking in the performance of household tasks, halls and doors should be so located that internal circulation is direct and access to outside entrances (both front and rear) convenient, especially from the kitchen. Door swings should be so arranged as to minimize interference with other doors, with furniture placement, or with circulation. Easy access to the ground is important to the housewife when she has packages to carry in, the baby to be sunned, or washing to be hung out. Walk-up apartments should therefore be limited in height to 3 stories.

So far as storage is concerned, home economics authorities emphasize the

need for a closet or wardrobe at least 22 in. deep and 3 ft. or more in width for each bedroom, cupboard space in the kitchen (protected against dust and flies), provision for storing brooms and ironing-boards, and additional general storage space for miscellaneous objects other than personal clothing and kitchen equipment. In multiple-dwellings a common storage space for baby carriages and bicycles should be provided, accessible by a ramp if not at grade.

From the standpoint of equipment, the kitchen should be provided with a suitable range. In urban areas a gas or electric range is desirable, which must meet the standards of safety discussed in a succeeding paragraph.

There should be a kitchen sink with a draining surface at the left, with the bottom of the sink set at a height of approximately 32 in., to avoid the strain involved in a low sink. Other work surfaces should not be higher than 34 in. above the floor.

Where laundering is done on the premises, a laundry tub and available drying facilities are essential. In multiple-dwellings, common laundries should be provided only if it is probable that they will be used by the prospective occupants.

The convenient disposal of garbage and refuse is important for many reasons, including maintenance of self-respect, control of flies, rats, and other vermin which may spread disease, and avoidance of fire hazards. In congested areas, a sanitary non-absorptive receptacle for garbage is an essential part of house equipment, and in multiple-dwellings special chutes discharging into incinerators have been found desirable. The best type of outside garbage receptacle is one that is set below the ground surface and protected from access of animals. A separate receptacle for ashes and rubbish should be provided where necessary, protected

against dissemination of its contents by the wind.

Principle 13. Provision of facilities for maintenance of cleanliness of the dwelling and of the person

a. *Specific Requirements*—Cleanliness of the dwelling depends in part on such construction as will facilitate cleansing; both dwelling cleanliness and personal cleanliness demand an ample supply of water (20 gallons per capita per day is a minimum for household use), with facilities for heating water. The ends in view are justified in part by the rôle of clean hands in preventing the spread of germ diseases, but on an even wider base they may be considered essential to self-respect from a psychological standpoint.

b. *Methods of Attainment*—To facilitate household cleansing, interior surfaces should be as nearly impervious, and joints between surfaces as tight, as is reasonably practical. Design should minimize dust-catching angles and pockets. Surfaces should be readily washable.

A safe water supply, adequate in quantity and under pressure, should be available within the dwelling. Where water has to be brought in by hand it will not be used in amounts necessary for cleanliness. Anything short of a pressure supply is a sub-standard compromise.

A bathtub or shower should be provided for each family where a pressure water supply is available, in addition to a wash basin.

Finally, at least a minimum supply of hot water is an essential of sanitary decency. This may be provided in the very low-cost rural home by heating water on the stove, but a hot-water heater is a basic element in really satisfactory housing.

Principle 14. Provision of possibilities for reasonable esthetic satisfaction in the home and its surroundings

a. *Specific Requirements*—It is obvious that matters of taste cannot be crystallized in quantitative terms, but it may properly be emphasized that the desire for beauty is a fundamental psychological urge whose satisfaction, in some degree at least, is essential to healthy living in the full sense of the term.

b. *Methods of Attainment*—The attainment of the ends suggested involves the application of taste and skill in community planning, in landscape design, in architecture, and in decoration, with due reference to the fact that variety is as essential as harmony in such a field. The difference in construction costs between an ugly and a beautiful building need not be appreciable, and the extra cost of brains used in planning is, in this case, relatively a very minor factor.

Principle 15. Concordance with prevailing social standards of the local community

a. *Specific Requirements*—Requirements here are obviously purely relative. It should, however, be pointed out that the sense of inferiority developed in a home notably below the standard of friends and neighbors may, and often does, produce emotional reactions, particularly in children, which are fundamentally incompatible with mental health. The public has developed a keen sensitiveness to the dangers of communicable disease, but still fails to realize the importance of emotional hazards. Under modern conditions of American living, a sense of inferiority due to living in a substandard home may often be a more serious health menace than any insanitary condition associated with housing.

b. *Methods of Attainment*—These again are relative and cannot be stated in any general terms. It is important that housing plans should take into account local social and racial stand-

ards which may profoundly modify the applications of the principle under discussion.

Social standards of a given area should be protected by proper zoning ordinances.

SECTION C

PROTECTION AGAINST CONTAGION

Principle 16. Provision of a water supply of safe sanitary quality, available to the dwelling

a. *Specific Requirements*—The water supply system should be so located, constructed, and operated that the water supply will not be a means of conveying disease; and the water should be devoid of objectionable chemical and physical characteristics. In some localities, it may be impossible to obtain water that meets all of these requirements, but in any case only a water that is safe from a public health point of view should be used. The standards established by the U. S. Public Health Service for drinking water served on inter-state trains may be used in determining the safety of the supply.

b. *Methods of Attainment*—The ideal is, of course, a communal supply whose sanitary quality is approved by health authorities. The availability of such a supply should be an important factor in selecting sites for housing projects.

Where individual supplies are the only ones obtainable, a properly protected spring or well is ordinarily the best solution of the problem. Surface supplies cannot practically be made safe for the individual household. The conditions necessary to insure a sanitary well supply are outlined in the Progress Report of the Committee on Ground Water Supplies of the Conference of State Sanitary Engineers for 1936, published as Supplement No. 124 of *Public Health Reports* (U. S. Public Health Service).

Principle 17. Protection of the water supply system against pollution within the dwelling

a. *Specific Requirements*—This principle requires construction of house plumbing in such a way that the water cannot be contaminated by cross-connections, by siphonage from bowls, tubs or toilets, or by drip into water reservoirs.

b. *Methods of Attainment*—Direct cross-connections or contamination of water reservoirs can be avoided by proper initial construction and by routine inspection of large installations by health departments to check on alterations. To avoid one common and possibly serious source of contamination—back-siphonage of polluted water into the supply—all fixture inlets which are directly connected to the supply system should be at a sufficient distance above the possible water level attained in the fixture itself to prevent contact. Numerous types of lavatories, drinking fountains, and other fixtures now in common use (and even some of those installed in recent public housing projects) violate this principle, although safe equipment is on the market. While it is unreasonable to demand remodeling of existing fixtures, this problem should receive attention in all future construction or replacement.

Principle 18. Provision of toilet facilities of such a character as to minimize the danger of transmitting disease

a. *Specific Requirements*—This principle involves, on the one hand, pre-

vention of spread of infection by flies or other insects and, on the other, reduction of the likelihood of transmitting intestinal or venereal diseases by contact.

b. *Methods of Attainment*—The ideal method of controlling access of insects to fecal discharges is the water-carriage system of sewerage, and housing projects should—so far as is possible—be located where such facilities are available. For the isolated home where water carriage is impossible, a sanitary privy so constructed as to protect fecal deposits from access of flies, and so located as not to endanger a water supply, is obviously a minimum essential. The type of privy recommended by the U. S. Public Health Service may be used where this method of disposal is unavoidable.

A separate toilet for each family would seem to be essential to insure responsibility for cleanliness as well as to promote decency.

Toilets should be located at a sufficient elevation above the sewer level to avoid back-flooding.

From the standpoint of avoiding venereal disease transmission, the toilet seat should be of an open-front type.

To avoid dangers of infection from contact with fecal matter, the walls and floor of the toilet compartment should be of material which is as nearly impervious as possible. Good lighting of the compartment is essential, since visibility is a major factor in stimulating habits of personal cleanliness. Artificial lighting alone is unsatisfactory on account of maintenance problems; a window opening to the outer air should be considered a minimum essential for all new construction. If the toilet compartment has a window opening to the outer air, no special provision for ventilation is necessary. Furthermore, many plumbing codes—based on the "sewer-gas" fetish—require quite unnecessary construction

costs (as for back-venting). The *Recommended Minimum Requirements for Plumbing* published by the National Bureau of Standards in 1931 should be used for the revision of such codes.

Principle 19. Protection against sewage contamination of the interior surfaces of the dwelling

a. *Specific Requirements*—This principle involves tightness of the house drainage system and construction of the main house drain and the external sewerage system so as to avoid back-flooding.

b. *Methods of Attainment*—Leaks of sewage on cellar floors, work surfaces, or elsewhere can be avoided by tightness of construction. To prevent the backing up of sewage into the dwelling, care should be exercised in selecting sites where adequate sewage disposal facilities are, or can be provided. Preference should be given to locations where separate systems of sanitary and storm sewers are available and to locations where ample fall can be obtained between the basement floor of the dwelling and the street sewer. Where such separate systems are in use, storm water from the roof and surface drainage should be conducted to the storm water sewer, and domestic sewage and basement drainage only allowed to enter the house sewer. Where necessary, the hazard of back-flooding the basement may be minimized by (1) installing an automatic back-water valve and a gate valve on the branch drain to which basement plumbing fixtures are connected, or (2) connecting the outlets of basement plumbing to a sump equipped with a suitable automatic pump or ejector which is arranged to discharge into the building sewer.

In the case of an isolated dwelling which is provided with an individual sewage disposal system, only domestic sewage and basement drainage should enter the system.

Principle 20. Avoidance of insanitary conditions in the vicinity of the dwelling

a. *Specific Requirements*—Where a cesspool or local sewage disposal plant is maintained, it must be so designed and operated as to avoid exposure of sewage which will permit transmission of disease by contact, by flies, or by pollution of wells; and the neighborhood must be kept free from accumulations of refuse which will afford food or harborage to flies or rats, and from standing water in which mosquitoes may breed.

b. *Methods of Attainment*—Where a cesspool or a local sewage disposal system is used, certain principles concerning the location and construction of such installations should be observed (such as location and depth of sewer; pipe sizes, materials, and jointing; and location, capacity, and covering of tanks). State health departments usually provide specifications in regard to these points. This committee is preparing suggested minimum standards for the location and design of sewage disposal systems for isolated dwellings where a settling tank and soil absorption system is used. The possibility of contaminating wells through the soil should be avoided in locating privies and sewage disposal systems. (Particularly in clay or limestone regions, available soil absorption capacity in relation to population should be considered in choosing a housing site.)

Accumulations of organic refuse which will breed flies should be avoided by provision of facilities for the removal and disposal of such refuse. Accumulations of rubbish, piles of lumber, etc., may provide harborage for rats and should not be permitted.

Stagnant water should, where possible, be removed by drainage or filling; bodies of water which cannot be removed and which are of a character to permit mosquito breeding should

be treated by appropriate anti-larval methods.

Principle 21. Exclusion of vermin which may play a part in the transmission of disease

a. *Specific Requirements*—This principle is concerned primarily with protection against mosquitoes, flies, and rats.

b. *Methods of Attainment*—Where mosquitoes and flies are present, all doors, windows, and other openings should be screened with No. 16 wire mesh. Screen doors should always open outward and should be self-closing. It is preferable to screen an entire window rather than only a part of it.

Where the rat problem is appreciable, care should be taken to close effectively all openings through foundations and floors, such as openings around pipes and cracked walls. Such openings should be closed with metal sheeting or concrete or other suitable rat-proofing material, such as asbestos board. Basement windows should be covered with strong, durable screening, such as standard 8-mesh galvanized hardware cloth. Ventilators and sewer openings should be provided with gratings. Exterior doors should be self-closing. The building foundation should be of concrete or masonry (or otherwise rendered rat-proof) and should extend (aside from frost or structural load considerations) from a point at least 2 ft. below ground to a point at least 2 ft. above ground. In case the floor is closer to the ground than 2 ft., the space in the walls between the studing should be filled with concrete, or other material indestructible by rats, up to a point 2 ft. above ground level.

Where the population to be housed is likely to be infested with vermin, provision may have to be made for fumigating clothing and furniture before occupancy is permitted.

Principle 22. Provision of facilities for keeping milk and food undecomposed

a. *Specific Requirements*—Various bacteria which cause food poisoning may propagate in foods which are not adequately cooled. Every home should have facilities for holding perishable foods at 50° F. or below.

b. *Methods of Attainment*—Either a mechanical refrigerator or a suitably constructed ice refrigerator should be considered an essential element in home equipment. Even in northern climates this will be necessary in summer. Refrigerator sizes should be adapted to family sizes; 4 cu. ft. of food storage space is ordinarily required for a family up to 5 persons.

Principle 23. Provision of sufficient space in sleeping-rooms to minimize the danger of contact infection

a. *Specific Requirements*—Experience in barracks and institutions has shown that a distance of less than 6

ft. between the centers of adjoining cots or a space of less than 50 sq. ft. per bed may lead to the spread of communicable diseases by dissemination of mouth spray from an infected occupant. The distance of 6 ft. between the centers of adjacent army cots would imply at least a 3 ft. space between the beds themselves, which is the essential point.

b. *Methods of Attainment*—To make it possible to meet the requirements above, the sleeping-room should therefore have at least 50 sq. ft. of floor space per occupant. This space is also required for placement of ordinary bedroom furniture. Assuming the customary minimum ceiling height of about 8 ft., this requirement checks with the standard of 400 cu. ft. per person suggested on other grounds.

Double-deck beds, sometimes advocated as a space saving device, are undesirable as favoring mouth spray infection.

SECTION D

PROTECTION AGAINST ACCIDENTS *

Principle 24. Erection of the dwelling with such materials and methods of construction as to minimize danger of accidents due to collapse of any part of the structure

a. *Specific Requirements*—These are being studied by the Building Code Correlating Committee of the American Standards Association, whose program includes standards for excavations and foundations, masonry work, iron and steel work, and structural loads.

b. *Methods of Attainment*—The ways in which such safety requirements can be translated into practice are

obviously too complex to be cited here. In view of current interest in the problem, a word may be said as to the structural menace of termite infestation. In zones where such infestation is serious, special provision should be made for termite control by constructing foundations of impenetrable concrete or masonry, and by removing stumps, chips, and litter from beneath the house. Adequate ventilation should be provided for the space beneath the house; vents should be screened; the clearance between the ground and the outside of the foundation and 18 in. inside; and for the most effective protection, termite shields of copper or other durable metal should cap the

* The importance of this problem is indicated by the fact that in 1936 home accidents in the United States caused 38,500 fatalities as compared with but 37,800 motor vehicle fatalities.

foundation wall. For complete protection, these shields should be continuous and extend entirely across the foundation wall, should project 2 in. or more on either side, and should be bent down at an angle of 45°. All posts, piers, pipes, and other structural members in contact with the ground should be shielded with projecting caps or collars. Surfaces that are difficult to inspect should be given the most thorough protection.

Principle 25. Control of conditions likely to cause fires or to promote their spread

a. *Specific Requirements*—All that can be insisted on—from the standpoint of protecting the lives of occupants—is that dwellings shall be so constructed and equipped as to minimize the probability of starting fires, and that the spread of fires shall be sufficiently retarded to permit the escape of occupants. Local building codes may require that dwellings shall not collapse for a period of several hours under fire conditions so extreme as to preclude the survival of any occupant. Such requirements, which add to the cost of building, must find their justification on other grounds than those of human safety.

b. *Methods of Attainment*—Potential sources of fire within the dwelling exist in electric installations, stoves and furnaces and their smoke-pipes, and in chimneys. Prevention of electrical fires calls for such details of construction as will control danger of crosses and the avoidance of exposed wiring subject to short-circuiting through wear. These factors are adequately dealt with by the usual local electrical codes. Stoves or furnaces should be mounted clear of combustible walls and floors, and if located near woodwork, should be insulated from it by adequate air space and by mats or screens of non-combustible material. Smoke-

pipes should be securely supported, well separated from woodwork or other inflammable materials, and kept clean. Where such a pipe must pass through a combustible partition, a ventilated thimble should be used to provide an air space around the pipe. Stove-pipe openings in chimneys should be covered when not in use.

Chimneys should be so constructed and supported as to avoid danger of overheating adjacent combustible elements. Masonry chimneys should be lined with fire-clay tile, with joints staggered in relation to masonry courses. Wood beams, joists, or partition members should be placed at least 2 in. away from chimneys, with the intervening space mortar-filled or otherwise effectively insulated.

In order to prevent the spread of fire originating within the structure, safe practice demands that in multiple-dwellings (regardless of height) the following elements be of non-combustible construction: exterior walls, roofs, first-tier beams, partitions between apartments and between stair halls and apartments, and all shafts. It is hardly less desirable that all floors and floor joists also be non-combustible. Certainly all multiple-dwellings exceeding 3 stories in height should have non-combustible floors and floor joists, and all those exceeding 4 stories in height should be fire-proofed throughout. Walls and partitions may be of brick, hollow tile, reinforced concrete, or other materials which upon test show that they will resist fire or delay its spread for a sufficient time to permit the escape of occupants.

For single-family dwellings of low cost, such fire-resistive construction may not be feasible, but fire hazards should be restricted through care in the installation of stoves, chimneys, and electric wiring as described above, through fire-stopping, and through reasonable precautions in the construc-

tion and finishing of roofs and walls.

Where framing with combustible members involves hollow wall spaces, the spread of fire can be retarded by closure of these spaces with fire-stops at the floor, wall, and roof lines. Well fitted boards can serve as temporary checks, but better results will be obtained by filling the voids with non-combustible materials for a distance of 4 in. or more above the fire-stops.

Fires are commonly spread from building to building by brands or radiant heat. Most of the non-combustible types of roofing have sufficient insulating value to prevent ignition of the boards supporting them by either of these means. The protection afforded by metal roofings can be increased by placing asbestos felt between the roofing and the boards. Wood shingles should not be used on account of their poor resistance to brands; once afire, they may themselves give off flying brands and set fire to neighboring structures. Weathered wood shingles are particularly subject to ignition by brands.

Among the common exterior wall materials, the range in fire resistance begins with board finish and runs in order through phenol plywood, stucco on wood lath, stucco on metal lath, and masonry veneer over wood frame, to load-bearing masonry walls. Well maintained paint coatings will slightly increase the fire resistance of a wood surface to exterior fire sources.

It should be a routine requirement that inflammable buildings be spaced far enough apart to prevent the spread of fire by radiant heat.

Fire-fighting provisions which are usually necessary include reasonable accessibility of each dwelling to fire-fighting vehicles and an adequate water supply for fire apparatus. The provision of chemical fire-extinguishers may be justified in the halls of multiple-dwellings.

Principle 26. Provision of adequate facilities for escape in case of fire

a. *Specific Requirements*—In every living-unit, the existence of exits which will not be cut off in case of fire should be regarded as a minimum essential; and these exits should be of such a nature that they can safely be used by women and children and at night.

b. *Methods of Attainment*—Multiple-dwellings should be provided with at least two means of exit from each living-unit. For reasons of economy in construction, exception may reasonably be made in the case of multiple-dwellings of 4 stories or less which are of fire-proof construction and provided with stairways in separate fire-proof enclosures having self-closing doors at each floor; compromises may also perhaps be made in certain cases of 2 story non-fire-proof buildings.

In multiple-dwellings, the doors of public exits should open outward.

Where local ordinances require outside fire-escapes, these should be constructed in accordance with the *Building Exits Code* of the American Standards Association. It is vital that fire-escapes should terminate on solid level ground or pavement in locations from which egress is unencumbered.

It is important to note that many types of drop ladders now permitted by local codes are so heavy and difficult to manipulate (particularly when rusted or heavily painted) that only a trained athlete can be expected to use them. The danger from such devices to a woman or child on an icy night is very serious.

Principle 27. Protection against danger of electrical shocks and burns

a. *Specific Requirements*—The requirements as to structural installations (aside from fire hazards) are two: (1) Live conductors and live parts of electric equipment should not be exposed to contact. (2) Exposed metal en-

closures should be grounded so as not to become alive from failure of insulation. Portable appliances and pendent fixtures should be so placed that a person will not simultaneously come in contact with electric fixtures and with plumbing fixtures or other grounded metal.

b. *Methods of Attainment*—In bathrooms, laundries, kitchens, or other spaces where the hands are likely to become wet, electric lights should be controlled by wall switches or pull chains containing insulating links, and any lamp sockets within reach should have non-metallic shells. Convenience outlets in such spaces should be located so as to minimize the probability of touching plumbing fixtures while using electric appliances. Convenience outlets should not be located in baseboards but high enough to be out of reach of creeping infants, which placement also brings them within more convenient access for the user. Any permanently installed electric heater should have a protective grating to prevent contact.

Principle 28. Protection against gas poisonings

a. *Specific Requirements*—The chief toxic substances likely to be associated with the dwelling are carbon monoxide from imperfect combustion in cooking or heating appliances, leaking gas from fixtures, and toxic gases from certain refrigerating devices. The control of such hazards is obviously essential.

b. *Methods of Attainment*—Any gas cooking-ovens and space heaters which involve the possibility of partial combustion must be provided with an adequate flue opening to the outer air. Chimneys, furnaces, and stove-pipes should be maintained in a tight and clean condition, as should gas connections and gas heating appliances.

Where toxic gases are employed in multiple refrigerator installations, special attention should be paid to tight

and durable jointing, and a warning gas should be added to odorless toxic refrigerants (in replacing routine leakage as well as in the original installation). Rooms which contain gas cooking appliances or mechanical refrigerators should not be used for sleeping.

Precautions against carbon monoxide poisoning in a domestic garage are an obvious need, but ordinarily involve no special structural provisions.

Principle 29. Protection against falls and other mechanical injuries in the home

a. *Specific Requirements*—Hazards of this type are too diverse to be catalogued, but it is clearly essential that stairs, windows, and balconies should be so constructed as to minimize danger of falls. In view of the many serious falls which occur in the bathtub, this problem should be kept in mind in planning the bathroom. Protection should also be given against injuries on outside steps and walks.

b. *Methods of Attainment*—A stairway should not be made too steep, and a proper proportion should be maintained between the dimensions of riser and tread. Satisfactory values are 7 to 7½ in. for the riser and 10 in. for the tread. In any case, these values should meet the conditions that the sum of the tread and twice the riser equals 24 to 25 inches, and that the angle of slope is between 30° and 36°. Steps of a flight should be uniform in dimensions, as any irregularity may cause tripping.

It is essential to provide every flight of stairs with a handrail. Outdoor steps especially need rails in northern latitudes, owing to ice.

Winding stairways too narrow for foothold at the rail side must be avoided, as they particularly invite falls. If a doorway is placed at the head of a flight of stairs, which practice has merit from the standpoint of

preventing the spread of fire, there should be a landing at least 30 in. wide on the stair side of the door. If this landing is omitted, the door should have a glazed window.

Low window sills (less than 30 in. from the floor) should be avoided, especially at stairway landings. If unavoidable, low windows may be provided with one or more cross-bars to prevent children from falling out. Built-in window screens have advantages, from the casualty prevention viewpoint.

Casement windows, if designed with sufficient clearance at the hinge to permit washing from the inside, will minimize dangers in window cleaning.

There should be railings or parapets around porches, balconies, accessible roofs, etc., high enough (at least 30 in.) to prevent falling off the edge. Such falls may cause serious accidents even when the distance is not more than 2 or 3 ft.

In bathrooms, especially where built-in tubs are installed below tiled walls, built-in hand-grips should be provided, sufficiently in front of the bather's position to be within convenient reach.

In the North, sloping roofs (with a pitch of perhaps from 15° to 55°) which end over steps or walks should be equipped with snow guards to prevent masses of snow from sliding onto the head of the passerby.

Adequate lighting of exterior courts, walks, and particularly of steps, is an essential safety factor.

Principle 30. Protection of the neighborhood against the hazards of automobile traffic

a. *Specific Requirements*—Attainment of this ideal must obviously be relative, and no specific standards can be set.

b. *Methods of Attainment*—Traffic regulation is an essential element in modern community planning; and it is particularly important that traffic in the vicinity of dwellings should be so organized as to minimize danger to both motorists and pedestrians (particularly children).

Residential streets should therefore be so planned as to discourage through traffic. It is often possible to do this in new housing communities by means of dead-end streets. Blind corners should be avoided by proper study of both building placement and shrubbery.

Pedestrian routes from all residential areas should be so planned that elementary schools, local shops, playgrounds, etc., may be easily reached without crossing any major traffic way except by the use of overpasses or underpasses.

Playgrounds should be effectively screened off from automobile ways.

“ STRENGTH IS INCAPABLE OF EFFORT, WEALTH
USELESS AND ELOQUENCE POWERLESS
IF HEALTH BE WANTING ”

ON September 30, the English launched a six months campaign devoted largely to health education.¹ Beginning in October, several hundred meetings will take place throughout that country, occupying “some 80 health days,” including the showing of films to school children, luncheon hour talks to factory and store employees, afternoon addresses to mothers, etc. There were many distinguished speakers at the opening Conference, and the report is full of meat. The claim was made by one speaker—with a great deal of truth we believe—that the English government, the local authorities, voluntary organizations and workers, and the medical and allied professions, have for some time been building up a network of health services which is probably not equalled by any other country today.

In spite of all this the Chairman of the Council of the British Medical Association said, “The respect paid to preventive medicine in medical education today is lip service only.” There is a certain amount of learning which is necessary to pass the examinations and the charge is made that that is the chief object of the student in these courses. The Chairman also said that “neither the teachers nor the examiners had any close acquaintance with the machinery of public health service, and the senior student is not taught, as he should be, his relationship to the profession as a whole, to the public, and to the State.” Even allowing for some pessimism, we fear this is too true and that almost the same statement can be made for America. Indeed, in America we are more “practical” and even more apt to be concerned in the money making side of our profession than our confreres in England.

The statement was also made that there was never a time when young people especially were so much interested in the health matters, being keen to preserve and improve their physical health by proper clothing, exercise, etc. It was pointed out that one great drawback was that so much of the advice came from the proprietors of commercial products whose motives were not disinterested.

"The remedy is to drown the voice of selfish interest in a stream of unbiassed advice whose sources are unimpeachable."

Sir Philip Henriques laid stress on the fact that good public relations depend upon encouraging not merely the use but also the appreciation of the health services offered. For years it has been the habit of the writer to devote a lecture in a class on preventive medicine to the health services offered by the federal, state, and local governments. He has often observed that the average person does not know where to apply for information on health matters. At several universities perhaps more applications for examination of water and advice on health matters go to the agricultural department than elsewhere, probably due to the extension services which are so numerous and active, and this is true even of some universities having medical departments.

One of the speakers laid stress on the part to be played by the family doctor in the health campaign. He compared regimentation such as was carried on during the Great War with the results of individual appeal, such as can be made by the family physician. In Great Britain the feeling is strongly against regimentation and in favor of individual appeal. Lord Horder said, "To endeavour to make a nation fit by this method (individual appeal) is the last test of democracy." He stressed also that length of life was not the most desirable thing. He said what he had in mind when he spoke of fitness was "health and happiness," and that the chief object of a good administration should be to make life better and happier for the individual. "Better and happier" should be synonymous with "healthier." While in agreement with these statements, in this country certain of us have stressed the idea of efficiency, and still think that is probably the best term to cover what is meant.

In America while health education is not being neglected, special stress is at present being laid upon certain diseases, notably syphilis and pneumonia. There can be no question of the value of these campaigns, as well as others along similar lines—malaria, for example—but after all, we are somewhat inclined to favor the English plan and English ideas rather than our own, never forgetting—what we have said, many times—that in our Public Health Service, we believe that we have the largest and best trained body of sanitarians in the world. We are all, however, working toward the same end and each of us can learn from the other. Just at present we feel that the English method is more fundamental and goes to the root of things somewhat more than what we are doing in America.

SANITATION IN THE NEXT WAR

IN the present turbulent state of world affairs, war seems, unfortunately, to be more than a remote possibility. If this country should be forced into another conflict, the plans of our War Department call for the almost immediate mobilization of 300,000 citizen soldiers, and the mobilization of an army of 1,250,000 within four months.

The sudden assemblage in hastily prepared camps of such a vast army of young men who are more or less susceptible to various diseases will confront our military and civilian authorities with certain acute public health problems.

years been investigating the efficiency of various serological tests and the Laboratory Section of the American Public Health Association has been studying the problem since 1922. The U. S. Public Health Service is now also engaged in an evaluation of the serological tests for syphilis performed in this country. The Laboratory Section, at the 1937 meetings in New York City, passed a resolution sanctioning the recommendations made by Dr. Parran and his collaborators.¹ The Referee for this section on serological tests for syphilis, in her report for 1937,² suggested that further requirements in regard to personnel and additional facilities might be advantageous. The Associate Referee explained the value of the quantitative test in the evaluation of the significance of the laboratory findings.³

The means proposed for achieving higher standards of work differ chiefly in regard to the placement of responsibility. While the importance of the proper training of technicians requires no emphasis, the need of adequate supervision of the laboratory as stressed in the report of the referee is essential. For ultimate success, the director of a laboratory must have had appropriate training and experience and assure himself that members of his staff are thoroughly capable of performing the duties assigned to them. The provision of standard sera has been most helpful in the production of antitoxins; similarly, reliable sources of reagents for serodiagnostic tests should be of equal importance.

With the development of methods which permit a quantitative determination of the activity of the serum in the complement-fixation test for syphilis, it is possible to report to the physician a numerical value which is a direct index of the titer of the serum. Such data promise to be increasingly helpful, not only in diagnosis but in prognosis and as a guide for treatment.

These problems cannot be considered without attention being paid to the cost of the work. Sufficient funds should be available to provide adequate facilities, and to maintain a competent staff with sufficient personnel to permit careful work. False economy never pays; it is particularly dangerous when applied to the laboratory.

CHEMOPROPHYLAXIS IN POLIOMYELITIS

IN 1935 workers at the National Institute of Health¹ announced that certain astringents introduced into the nostrils of monkeys tended, during a limited interval, to prevent the development of intranasally inoculated poliomyelitis.

This fact has been further elucidated at the National Institute of Health²⁻⁴ and confirmed and extended by independent workers, notably at Stanford University⁵⁻⁹ and at the Rockefeller Institute for Medical Research.^{10, 11}

This protection is believed to depend upon a local action of the chemicals upon the terminals of the olfactory nerves which apparently constitute the portal through which the virus reaches the central nervous system in intranasally inoculated monkeys.

Whether chemoprophylaxis will prove effective against naturally conveyed poliomyelitis in man can only be determined by extensive controlled field trials employing a method of application capable of completely covering the olfactory area in a high proportion of persons treated. The finding of such an effective method of application has proved difficult. The ordinary atomizer as employed in Alabama, Tennessee, and Mississippi in 1936 proved ineffective.¹² Judged by the loss in the sense of smell, the method devised at the University of Michigan was effective in completely covering the olfactory area in only about 24 per cent of persons to whom the 1 per cent zinc sulphate-1 per cent pontocaine spray was administered at Toronto during the 1937 outbreak.¹³

Failure of thorough application of chemicals to the olfactory areas, therefore, offers a possible explanation for the poor showing of the method in these field trials where the apparent reduction in poliomyelitis among the sprayed as compared to the unsprayed group was so slight as to be statistically inconclusive.

The Toronto applications were made by the method devised at the University of Michigan¹⁴ which employs a special spray tip inserted past the middle turbinates, which constitute the chief obstruction preventing ordinarily applied sprays from reaching the olfactory area. This method was advocated for use by specialists only but was found to be too time consuming to be a practicable procedure in the face of an epidemic; furthermore, its application is difficult in children too young to coöperate by holding still.

The spray is not pleasant to take and is often followed by varying degrees of local burning and headache lasting from a few minutes to several hours. Moreover, these unpleasant features which were most usually noted in adults might have been even more in evidence had the application been more uniformly thorough. Following the zinc sulphate sprays, loss of smell in varying degrees was commonly noted and, in some instances, the impairment persisted for a number of weeks. Serious permanent injurious effects were not observed, however, in any case.

Attempts to find a simpler, more satisfactory effective method of covering the olfactory areas in man are being made and it is to be hoped that they may succeed in order that chemoprophylaxis may be finally evaluated and possibly further light be thrown upon the method of natural infection for poliomyelitis in man.

THE USE OF ANTITYPHOID VACCINE DURING EPIDEMICS

THE health authorities in England are very much disturbed over the outbreak of typhoid fever in Croydon, which is practically a suburb of London, while London itself has remained free from the disease. Hearings are being conducted and a number of lawyers representing several interests are taking part.*¹ According to the statement of the Health Officer in answer to questioning, the source of the epidemic has not yet been determined.

In the English journals much enlightening discussion is being carried on over the question of how to protect individuals who have already been exposed to infection. Is the use of antityphoid vaccine justifiable in these cases? Sir Almroth Wright laid considerable stress on the "negative phase" which followed the administration of any vaccine, holding that until the response took place and immune bodies were produced the individual had a lower resistance and was theoretically more liable to the disease than before.

In America this fear has not been allowed to have too much weight. In 1913, two outbreaks of typhoid fever occurred in Wisconsin, one in a county hospital and one in a village, in both of which antityphoid vaccine made after the method of Wright was used.¹ In both outbreaks the vaccines seemed to produce the most favorable effects. In the first there were 106 contacts vaccinated and 1 case of typhoid fever occurred after the vaccination. It was observed at the time that the case was mild and the comment was made that the vaccine seemed to exercise a favorable effect when given during the period of incubation. Certainly there was no evidence of harm being done. In the epidemic in the village, 116 contacts were vaccinated and 1 case of typhoid fever was reported among the vaccinated. In a report to the American Philosophical Society, the ground was taken that even where the vaccine failed to prevent clinical disease, it apparently had a good effect in modifying the severity of a subsequent attack. It is recognized that the cases observed were too few on which to base far-reaching conclusions, and further that there was no statistical analysis, such as that made by Ramsey.²

Perhaps the best study made on the effect of vaccine on contacts has been made in this country.² Vaccine was given to 2,402 household contacts, among whom only 9 subsequently went down with typhoid fever. Among 2,886 unvaccinated contacts, 203 had the disease. The author, Ramsey, pointed out that these figures were not comparable, but gave a correct analysis of his data as follows:

<i>Vaccination Status</i>	<i>No. of Cases</i>	
	<i>Expected</i>	<i>Observed</i>
After third dose	25.06	6
Between second and third doses	13.54	8
Between first and second doses	18.47	9

He believes that the figures from the first to second and from second to third doses of vaccine, the differences between expected and observed cases are of

* On the last day of the hearing (January 11) it was announced that the total cases numbered 290, no fresh cases having been notified for several days. The number of deaths was 38. A bulletin outside the town hall stated that 6 patients were still dangerously ill with typhoid at Mayday Hospital, and 7 others seriously ill.⁹

doubtful significance, but raises no question concerning those contacts who have received three injections, and concludes that among household contacts of primary cases which either remained at home or were hospitalized there is a reduction of 75 per cent from the expected secondary case incidence.

The discussion in the English journals is useful in bringing out a number of facts apparently not widely known, which we hope will for all time allay the fear of people over the "negative phase" as far as typhoid fever is concerned. In 1915, there were 14,836 Belgian civilians inoculated in Ypres in face of a danger very much more imminent than that in Croydon. Indeed, the Belgian Government made antityphoid vaccination compulsory with penalty of expulsion from the country. While the observations are not entirely exact, there is no known instance of increased susceptibility among the many thousands of persons vaccinated.³ Another writer challenges the opponents of vaccination of contacts to quote statistics in support of their view.

In contrast with the attitude of the *British Medical Journal*, is an editorial in the *Lancet*,⁴ which lays some emphasis on the "negative phase" following vaccination. "The transient effects of the negative phase, even if we regard them as negligible in an uninfected person, may well disturb an already changing balance between parasite and host to the disadvantage of the latter." This editorial fortunately brought out a very strong letter from Sir J. C. G. Ledingham,⁵ who says flatly that he is in complete disagreement with the ideas expressed in the editorial, and in general agreement with those of the *British Medical Journal* of the same date.

PROTECTION AGAINST POISON GAS

WE have called attention to the numerous notices of antipoisonous gas activities in England, which no doubt are a constant surprise to people in this country. The letters from England to the *Journal of the American Medical Association*, for example, frequently have items of some length on the movement. Gas masks are being manufactured by the millions and being distributed to the people generally, and studies are being made over one of the most perplexing problems; namely, how to protect infants and young children. The most recent report¹ is that the British Red Cross Society has awarded nearly 33,000 certificates for first aid in chemical warfare, of which 5,734 are held by students who have successfully completed the advanced course of training. In addition to this, the society now has 1,864 fully qualified instructors available for teaching.

Just what this all means is more or less of a puzzle, but it is evident that the authorities must believe there is a real danger which needs to be provided against.

LETTER TO THE EDITOR

TO THE EDITOR

THE very remarkable address of Miss Josephine Roche on "Medical Care as a Public Health Function," delivered at the New York meeting of the Association and published in the December issue of the *Journal*, closed with the following two paragraphs:

The situation calls for leadership. No one formula or program will probably be found adequate to meet our varied needs, but a composite of many efforts and plans, some in experimental stages, some not yet under way, can and must be found. What group is better fitted to lead and carry through than the public health profession with its medical personnel and its traditions of fair dealing with the public and the medical profession alike?

A far step forward would be taken, I think, if the American Public Health Association formally recognized the problem of the present unequal distribution of medical services, and the widespread human need of today, and charged a special committee to cooperate with the U. S. Public Health Service in extending through proper methods the long accepted functions of public health work to meet modern demands and needs of our people. I hope this action may be taken.

The Scientific Session immediately by unanimous vote, requested the Governing Council to authorize the appointment of such a committee. This was done by a resolution proposed by Dr. E. S. Godfrey, Jr., State Health Commissioner of New York, which reads as follows:

RESOLVED that a special committee of this Association shall be appointed to study the public health aspects of medical care and to cooperate with the United States Public Health Service and other Federal agencies represented in the President's Interdepartmental Committee on Health and Welfare, the American Medical Association, the American Dental Association, and other appropriate bodies in extending public health work to meet modern needs,

especially those occasioned by the increasing importance of chronic diseases as causes of sickness and death. Such committee shall be appointed by the Executive Board at its next regular meeting.

At the meeting of the Executive Board, Drs. A. T. McCormack of Kentucky, J. N. Baker of Alabama, and John L. Rice of New York, were appointed a committee to invite the cooperation of the U. S. Public Health Service, the American Medical Association, and other interested agencies, in a study of the medical and public health needs of the people of the several states. The committee met with the officers and the Executive Committee of the Board of Trustees of the American Medical Association in Chicago on December 20. Dr. C. E. Waller, Assistant Surgeon General, represented the U. S. Public Health Service at the Conference. In order that the American Medical Association might realize the acute problem that had been raised by Assistant Secretary Roche's address, Dr. McCormack read it in full and he and Dr. Baker presented certain preliminary data which should be explored and expanded by all the interested agencies. On behalf of the Public Health Service, Dr. Waller stated that the Service had no concrete plan for meeting the medical care problem to submit to the Conference at that time, but pointed out the urgent need of an immediate solution of the problem. He urged that both the Board of Trustees of the American Medical Association and the American Public Health Association give the problem their most serious consideration, and recommended that a study be undertaken to determine

more accurately the nature and extent of the problem—especially the need for more adequate medical service for the groups that cannot afford to pay for such service. Dr. Waller also made it clear that the Public Health Service does not favor any plan which would call for the socialization of medicine or for the regimentation of physicians in this country, nor does it advocate any change in the method of practice of medicine which would alter the present physician-patient relationship.

After full and frank discussion, the Board of Trustees of the American Medical Association adopted the following Resolution:

WHEREAS, a varying number of people may at times be insufficiently supplied with needed medical service for the maintenance of health and the prevention of disease; and

WHEREAS, the means of supplying medical service differ in various communities; be it

RESOLVED, that the American Medical Association stimulate the state and county medical societies to assume leadership, securing coöperation of state and local health agencies, hospital authorities, the dental, nursing, and correlated professions, welfare agencies, and community chests, in determining for each county in the United States the prevailing need for medical and preventive medical service where such may be insufficient or unavailable; and that such state and county medical societies develop for each county the preferable procedure for supplying these several needs, utilizing to the fullest extent medical and health agencies now available, in accordance with the established policies of the American Medical Association. Be it further

RESOLVED, that the Board of Trustees of the American Medical Association establish a committee to coöperate with the Bureau of Medical Economics in outlining the necessary procedures for making further studies and reports of the prevailing need for medical and preventive medical services; and that the Secretary of the American Medical Association arrange to develop such activities through the secretaries of state and county medical societies in each instance, urging the formation of special committees in each county and state where committees are not available for this purpose.

The American Public Health Association feels that Assistant Secretary Roche came to it as an official representative of the people of the United States and presented a case. The Association proposes to assist the U. S. Public Health Service, the American Medical Association, and other interested agencies in making a diagnosis of public health and medical needs in the United States. It is of the utmost importance that this should be done frankly and honestly and without preconceived and empiric notions as to the remedy that will be suggested; that will be a matter for the sound judgment of the national organizations involved.

As implied in the resolutions adopted by the Board of Trustees of the American Medical Association, the organized medical profession throughout the United States will be appealed to for the purpose of giving aid along two definite and concrete lines; first, to define more clearly the problem of medical needs as they relate to the several states and sub-divisions of government within the states; and, secondly, to develop procedures looking to an amelioration of existing needs.

The Governing Council in announcing its earnest purpose to coöperate with the U. S. Public Health Service, the American Medical Association, and such other agencies as may be invited to participate, desires that each public health agency, official and voluntary, in the United States, join in an earnest endeavor to see that a careful inventory of public health and medical needs of the people is made.

ARTHUR T. McCORMACK, M.D.,
Chairman

Committee on Public Health
Aspects of Medical Care

PUBLIC HEALTH EDUCATION*

For Kansas City in October—Examples of graphic and dramatic presentation from various cities and states would be timely at the A.P.H.A. meeting in October, 1938. There should be space at Health Education and Publicity Headquarters for showing displays and for staging demonstrations, usually not possible at the Annual Meeting.

Who does an effective bulletin board display in office, lobby, or in hallway of a city hall?

How does some one *effectively* display posters or placards at a clinic? (Not the unplanned posting of heterogeneous posters in any bit of vacant wall space.)

In what schools do social science classes produce graphic presentation of health facts?

Are there manual training classes or other craft groups which might become interested in the production of illustrative devices, doing a double educational job in the school, and making available unusual material to interest parents and other adult friends?

Are there health workers skilled with tools, camera, scissors, paste pot, pencil, or other equipment, who might experiment with graphic presentation?

Suggestions on any of the above possibilities will be supplied upon request to the editor of this department of the *Journal*.

What Is Visual Education and How?—The visual phase of health

education in schools has been but lightly touched by health agencies. The possibilities for coöperation with the schools will be developed in a later issue.

But whatever we do should be based upon an understanding of visual education as it is in at least the more progressive schools and school systems. For this purpose an invaluable aid is "Audio-Visual Handbook," by Ellsworth C. Dent, who has a long experience as a teacher of teachers and a leader in visual education.

The book tells concisely about the different visual mediums, how they are used in schools, how to make them or to assemble them. There are classified reading references, lists of sources of equipment and materials.

A paragraph from the chapter on "Organizing the Audio-Visual Service" is addressed to school people, but carries a message for health workers who seek to coöperate with the schools.

It has required several years of blundering and sometimes painful experience for schools and school systems to realize that visual instruction plans, to be effective, must take into consideration the curricula of the schools concerned, the general plans of the various departments, and the specific plans and needs of individual teachers. Otherwise, as actually happens when visual aids are used haphazardly, there will be waste of time, money, and teaching effort. All three are too limited to be applied in any but the most effective manner. . . .

This little volume promises to be useful to the national or state agency which would plan materials for school use; to the local executive or staff member who wishes to approach the schools with understanding and utmost help-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Routzahn, 130 East 22d St., New York, N. Y.

fulness. The worker in adult education will find much that may be utilized outside the schools. And it would seem that staff training on the job, and instruction in the professional school could be more interesting and effective in the light of what this book contains.

"The Audio-Visual Handbook." Society for Visual Education, 327 S. LaSalle St., Chicago, Ill. 182 pp. Paper, \$1.25; Cloth, \$1.75.

Talk Warily and Wisely — A "Social Hygiene Day" speaker referred briefly and almost casually to a high proportion of college students as having sexual experience, with the added statement that "girls are becoming less chaste and boys more so."

The newspapers, as representing the interests of the public, promptly followed this lead, and interviews flourished, headlines blossomed.

The immediate result seemed to be that public attention was diverted from the main issues to be emphasized by "Social Hygiene Day."

At any rate we have in this incident a fresh reminder of the danger when a speaker makes casual reference to spectacular situations, or makes broad factual statements for which there is but limited statistical evidence.

One might believe that social hygiene program committees should prepare carefully worded reminders or warnings to their prospective speakers. Included might be emphasis upon the need of avoiding incidental references to spectacular situations, where time or relevancy rule out carefully detailed statements.

Along with this should go a request that generalizations without accepted proof of their accuracy should be avoided.

Listeners and readers alike may easily pick out, isolate, and accept as being of major importance an idea or

a fact a long way from the central theme of the talk or paper.

If we fail to warn our speakers we should not quarrel with newspapers or audiences which miss something we believe to be of prime importance.

Don't Waste a Newspaper Man's Time—Get acquainted with your newspaper men and women, but be discreet in breaking in upon them during busy business hours—is one message from David Resnick in "Social Work and the Press," in *Better Times*, 44 E. 23d St., New York, N. Y. Feb. 7, 1938. 35 cents.

Much of the difficulty of social agencies is caused by ignorance of news values, inability to tell a story in journalistic language, or unfamiliarity with newspaper methods. If there is any secret of success in successful publicity, it is this: search for news, write it as a news story, send it in the mail, and trust to luck.

In order to get along with reporters and editors, it is often more important to know what *not* to do than what should be done. One reason for the irritation felt by reporters and editors is the waste of their time by health and welfare executives—and the amateurs in publicity—whose very important story is just another dull item to the newspaperman, for the latter is conditioned by daily contact with the varied and exciting happenings of our complex modern world.

Another mistake is to bother working newspapermen in their offices by dropping around—especially near edition time—with a statement or picture which should have been mailed, an idea for a feature, or a vague request for "coöperation." A minor but annoying offense is to call a newspaper man needlessly on the telephone—and break in on his writing or editing a story—to discuss something which should have been sent as a memo to be read at his convenience.

The come-back from some of our readers will be that *they know* their newspaper people, and know the welcome that is extended to them as health workers. Happy indeed is the lot of those who have such informal contacts. *But be sure that you do know.*

"Topics-of-the-Month" in Indiana—Says *Journal*, Indiana State Medical Assn., Indianapolis:

In the January issue of *The Journal*, there was outlined a plan for work for the year 1938, and the plan included the idea of selecting an appropriate subject for each month, to be emphasized on the President's Page, to be discussed in *The Journal*, and to be offered as a topic for discussion at one meeting of each county medical society during the month. It is suggested that each subject be presented in such a manner as to stress its economic and public health or community aspects. The next eleven months will have the subjects as given below, and they are given in advance so that each county medical society secretary can make use of them in preparing programs, and so that each physician can have an opportunity to prepare himself to discuss the subjects:

February—Syphilis . . . March—Pneumonia . . . April—Diphtheria . . . May—Maternal and Infant Mortality . . . June—Crippled Children . . . July—Highway Accidents . . . August—Occupational Diseases . . . September—Annual Physical Examination and Attention to Heart Diseases . . . October—Conservation of Eyesight . . . November—Tuberculosis . . . December—Smallpox.

"How to Win Prospects—And Influence New York's Health" is a small 4 page folder by Dale Carnegie, Chairman, Speakers' Bureau. United Hospital Campaign Committee, United Hospital Fund, New York, N. Y.

The 8 ways to help win people to your way of thinking which I outlined in my book, are the same 8 ways to help win gifts for the support of the essential health services protecting the people of New York.

Briefly repeated, these are as follows.

1. The only way to get the best of an argument is to avoid it.
2. Show respect for the other person's opinion. Never tell a man he is wrong.
3. If you are wrong, admit it quickly and emphatically.
4. Begin in a friendly way.
5. Get the other person saying "yes-yes" immediately.
6. Let the other man do a great deal of the talking.
7. Try honestly to see things from the other person's point of view.
8. Let the other man feel that the idea is his, not yours.

As far as gift solicitation goes, these 8 general methods of dealing with people may be narrowed down to 5 specific goals you will be shooting at. The goals will have to be reached one after the other, so I have attempted to list them below.

First—Know the facts. You know what the hospitals are and what they do. You know how they protect the community's health. You know the broader program of health protection which is being undertaken through integration of medical social service, convalescent care and home care with the active hospital treatment of the sick. You have made yourself familiar with this information at meetings and by reading the campaign literature. Aren't these facts, which convinced you, the same as will convince your prospect? So, Step One is: **KNOW YOUR FACTS.**

Second—Be interested in your prospect. You have studied his record to find out how much he should give. This interest in him will, in turn, help interest him in you and your appeal. Besides, it is what makes possible getting an early yardstick gift from your best prospect as a challenge to those you see later on. So, Step Two is: **STUDY YOUR PROSPECTS.**

Third—Remember the value of time. You cannot afford to take a chance on your prospect not being able to see you. So you make an appointment. Will not this make him realize the importance of your call? It will also ensure you an opportunity for personal solicitation. Let's call Step Three: **MAKE AN APPOINTMENT.**

Fourth—Know what is needed. You realize how much the hospitals dig into their own pockets for free care. You know that the 3-cents-a-day plan does not provide funds to meet these extra needs. You understand then why they need support. In the same way you can make your prospect realize why the hospitals need his gift and the gifts of the other executives of his company. Why they also need a corporate gift equal to \$4 for each of the company's employees. Step Four, then is: **GET BOTH EXECUTIVE AND CORPORATE GIFTS.**

Fifth—Have full confidence. There is no question in your mind about the need of the voluntary hospitals. Knowing their value, you have no doubt that the money will be raised.

My work in life has been to teach people the confidence they need for success. When they have that the battle is nine-tenths won.

You already have this confidence. That makes me, for one, sure of the campaign's

success. Sure that New York will have the continued protection of its voluntary hospitals. So Step Five is: LET'S START NOW, AND SEE OUR FIRST, AND BEST, PROSPECT TODAY.

Health Education in the Journal
—Health education material in *American Journal of Public Health*, Jan., 1938:

In "A State Cancer Program," by Chadwick and Lombard, on page 15, as one of 5 main features gives "Education of physicians and the laity regarding cancer." On pages 18 and 19 the present educational program in Massachusetts is considered.

In "Diabetes—An Important Public Health Problem," by Bolduan, the functions of a proposed, and now realized organization, is stated to include:

To carry on health education of the public in all matters pertaining to diabetes.

Under "Books and Reports" (pages 99–100) reviewers call attention to errors or omissions such as are so frequently mentioned under this heading. And, writers and publishers please note, such comment might easily have been avoided. These books needed more adequate editorial supervision, and more critical advance reading by outsiders before being put into final form.

In "A Selected Public Health Bibliography With Annotations," by Patterson, pages 104–105, are several references to education.

"Pneumonia Film," page 112, announces a new motion picture.

In *Hygeia* for Feb., 1938—*Hygeia* (535 N. Dearborn St., Chicago, Ill.) has bettered its cover pages by the use of photographs bleeding over one or more edges of the page.

Fourth of July accidents ("State legislatures should be informed of the facts and the most effective means of combating the menace") . . . Outwitting arthritis ("It can be done") . . . X-rays: a way to better

health through photography . . . Modern medical charlatans ("a word for the wishful") . . . Your age and your heart . . . This little pig (had trichinosis) . . . The choice of a marriage mate (10 point specification) . . . Eyes in industry (Effects of illumination) . . . Diabetes (and insulin) . . . Your skin (15 pictures) . . . Open wide! (Give the dentist a chance to serve you early) . . . "I'm not afraid of cancer!" (But, fight it!) . . . The story of human energies (The power plant illustrated) . . . First aid for fractures in skiing . . . Do you snore? (What to do about it) . . . Old dogs and new tricks (The story of Ivan Pavlov) Your health! (Health teaching helps by radio) . . . Questions and answers . . . New books on health.

In "School and Health":

Building the health curriculum in the high school . . . A dental score card for the junior high school (Malden, Mass.) . . . Body building and regulating foods . . . All in the day's work (Emotional problems met in Syracuse, N. Y.).

COMMERCIAL GADGETS

Some of us are pioneers in spirit; to experiment with the new is a delight. These adventures will test new devices, materials, processes, and, we hope, report the results in these pages.

The information offered under this heading comes from reputable sources, but usually it is all too new for the editor to give personal testimony.

Some of the commercial gadgetry will be found under "Exhibits," or other special headings.

You use pencils of 2 colors in editing copy, checking lists, correcting students' papers? Autopoint Co., 1801 Foster Ave., Chicago, Ill., now offers through local stores a "Two-color Autopoint," with selected colors indicated on the tips. Red, blue, yellow, green, purple, or black. Also hektograph leads.

The latest of numerous devices for fitting copy and type is "The Automatic Character-counting Roto-Typometer and Graphic Arts Calculator." Roto Calculating Devices Co., 354 Roger Williams

Ave., Highland Park, Ill. \$2.50. The 9 inch square device counts typewritten or printed copy by *number of characters* (not number of words which are so variable as to number of letters); gives amount of space needed in a given type face; and so on. A small 4 page folder tells how to make it work in solving copy fitting problems. The manufacturer will send "Roto-Typometer" on approval for examination and test.

Typewriting, carbon copies, drawings, etc., on any good grade of paper may be prepared easily and cheaply for blue-printing. The method may prove useful: to secure an extra copy or two of an important document for immediate use, or for preservation; as a novel form of presentation of important facts or statistics to a board or committee (budget committee of a community fund?); as a novelty invitation or announcement to a small group. The job is done by a diethyl phthalatesolox solution to the paper. For details address U. S. Industrial Alcohol Sales Co., 60 E. 42d St., New York, N. Y.

FOR EDUCATION AND REFERENCE

Modern salesmen in many lines are encouraged to carry ideas and information to pass on to their customers. Many of these salesmen are assured of a welcome because of the real help they bring along with their sales talk.

Increased interest and coöperation may be won by health salesmen who pass on selected copies of reprints, pamphlets, copies of radio talks, etc.

Under this heading may be found, from time to time, just what an alert editorial writer could use to advantage. Rotary president may welcome something else. Something may be found for the mayor, or the chamber of commerce secretary, or the woman's club program chairman. Such single items, handled by the health worker in retail fashion, may in time bring wholesale returns.

Of course much that is mentioned here will be of value only to administrator, the health educator, or some other staff specialist.

"A Baby Pays for Her Parents' Neglect" is an 8 page mimeographed booklet re-issued by the Middletown, N. Y., Health Dept. This anti-diphtheria document, written by Mildred D. Shelley, has been broadcast by Winston-Salem and Jersey City, reprinted by Rockford, and published in health periodicals in Washington, New York, and India. We are delighted to record such repeated use of good material. We hope for increased evidences of use of good copy produced in some other city or state.

"Beauty and Preventive Medicine," by C. H. Goodrich, M.D., President, Medical Society of State of New York. An argument for periodic health examinations. Reprint. Address the Society, 2 E. 102d St., New York, N. Y. *Free*.

"Child Labor Facts." The 1938 compilation. National Child Labor Committee, 419 4th Ave., New York, N. Y. *25 cents*.

"A Cold Can Rob You" is a bulletin board placard listing 10 precautions against colds. Employers Mutuals, Wausau, Wis.

Consumer Education Service, Am. Home Economics Assn., Mills Bldg., Washington, D. C. A monthly news letter. Health workers may be interested in the news from Food and Drug Administration and Federal Trade Commission, and of legislation, publications, etc., which have health angles. Hospitals and other institutions may learn about standards, grading, etc. Sample, *15 cents*.

"Methods and Equipment for Home Laundering." (*Farmers Bulletin* No. 1497.) U. S. Dept. of Agriculture, Washington, D. C. Includes section on handling infected clothes, from U. S. Public Health Service. *Free*.

"Publications" of Am. Home Economics Assn., Mills Bldg., Washington, D. C. *Free*. Classified list.

From American Social Hygiene Assn., 50 W. 50th St., New York, N. Y.:

"Facts About Syphilis." 4 pp.

"Facts About Gonorrhea." 4 pp.

"Safe Motherhood and a Healthy Child." 4 pp.

"Congenital Syphilis," by J. Marshall. 8 pp. Reprint. 5 cents.

"The Newest Generation," by W. F. Snow. 10 pp. Reprint. 10 cents.

Frequently single copies of federal government publications will be supplied free upon request direct to the government office where they originated, or to your Congressman. Early application is desirable.

For a list of state and city health councils, and minutes of the 1937 meeting of National Committee of Health Council Executives, address the secretary, Howard W. Green, Cleveland Health Council, 1900 Euclid Ave., Cleveland, Ohio.

"The Inside Story of the Depression" is an elaborate pamphlet of 32 pages, 8x10 inches, about a dozen X-ray pictures, which, with a facing page of text in the form of a case story, tells the story of health needs and medical service as they are faced by the Community Chest, Dayton, Ohio. Among the most striking of such appeals! Electrotypes, photographs, or printed pamphlet with local adaptation, may be secured through Social Service Feature Syndicate, Hotel Biltmore, Dayton, Ohio.

"Program for a General Health District and City Health District of Average Size." State Dept. of Health, Columbus, Ohio. 20 pp.

An "autographed steel engraving" of Dr. Edward L. Trudeau, about 11 by 14 inches, is offered for \$1.00 by National Tuberculosis Assn., 50 W. 50th St., New York, N. Y.

"Which One?" is a 4 page folder

on early diagnosis. "Your Child's Health" is a cyclopedic 6 page folder edited by Public Health Education Committee, Minn. State Medical Assn. Samples from Minnesota Public Health Assn., 11 W. Summit Ave., St. Paul, Minn. We are getting interested in how health agencies prepare the way for a hearing for the cyclopedic type of folder or pamphlet, or do we simply "give them out"?

American Medical Assn., 535 N. Dearborn St., Chicago, Ill., reprints from *Hygeia*:

"Bad Habits in Good Babies." 16 pp. 15 cents . . . "Marihuana." 2 pp. 5 cents . . . "The Truth About Candy." 4 pp. 5 cents . . . "What Science Knows About Cancer." 9 pp. 5½ by 8 in. 10 cents . . . "What Does Your Baby Put in His Mouth." 22 pp. 5½ by 8 in. 20 cents.

"Publications of Office of Education, 1930-1937." *Free* of Office of Education, Washington, D. C. Indicates free publications. These new titles probably *free* from the Office. Sold by Supt. of Documents, Washington, D. C.:

"Physical Education in Institutions of Higher Education." 32 pp. 10 cents . . . "Education of Negroes: A 5 Year Bibliography." 62 pp. 10 cents. Brief section on health . . . "Student Interests and Needs in Hygiene." 21 pp. 10 cents . . . "Educational Directory, 1938: Associations and Directories." 69 pp. 10 cents.

These U. S. Public Health Service publications are sold by Supt. of Documents, Washington, D. C.:

"The Bed Bug." 7 pp. 5 cents . . . "Public Health Nursing." 14 pp. 5 cents . . . "The Rat and Ratproof Construction of Buildings." 68 pp. 15 cents . . . "Some Public Health Service Publications Suitable for General Distribution." 21 pp. 5 cents.

National Organization for Public Health Nursing, 50 W. 50th St., New York, N. Y., reprints at 10 cents each:

"The Nurse Stimulates Employee Interest in Safety" . . . "A Study of Volunteer Services" . . . "Student Affiliation With a Public Health Nursing Agency."

For these reprints from "Hospital Survey of New York" address the author, Dr. E. H. L. Corwin, N. Y. Academy of Medicine, 2 E. 103d St., New York, N. Y.:

"Ambulance Service" . . . "Institutions for Convalescent Care" . . . "Control and Coördination Concerned with Organized Care of the Sick."

SAFETY

Accident Prevention Conference of Dept. of Commerce, Washington, D. C., has issued two well done booklets:

"How to Stop Farm Accidents." 22 pp. Free.

"How to Stop Home Accidents." 14 pp. Free.

In Nov., 1937, school children of New Milford, N. J., riding bicycles to school were required to have license plates on their machines, and to carry riders' licenses. B. F. Gibbs, supervising high school principal, engineered the plan as a safety measure. The license cards bear on the back a 14 point bicycle code.

A book bargain is offered by National Society for Prevention of Blindness, 50 W. 50th St., New York, N. Y. "Eye Hazards," by Resnick and Carris, is a \$1.50 book of 247 pages, except that some of the safety devices in the pictures are outmoded. The present bargain price is 50 cents.

A bulletin board poster attempts to make graphic the baffling characteristics of carbon monoxide gas. At one side of the poster are 4 blank white panels captioned: "What it looks like!" "What it tastes like!" "What it smells like!" and "What it feels like!" Employers Mutuals, Wausau, Wis.

An "Education in Accident Prevention" issue of *Journal of Educational Sociology*, 32 Washington Place, New York, N. Y., is dated Sept., 1937. 35 cents. Includes

Application of psychological methods to

safety education . . . The nonreduction of accidents . . . Mental hygienist looks at safety education . . . Education programs in Cleveland and Baltimore schools. The editorial urges the failure of "spread or transfer," and the resultant need of direct education. Says the editor:

The purpose of this agitational article, therefore, is to urge those interested in education in accident prevention to take the strict Thorndike point of view as a fundamental of psychology; to work from the Thorndike point of view and insist upon specific instruction to meet each specific accident situation of any importance.

The following subjects will be featured in the 1937-1938 issues of *Safety Education*, the magazine for home and school, 1 Park Ave., New York, N. Y. (sample upon request):

Oct., Fire prevention . . . Nov., Safety in the school shop . . . Dec., Holiday safety . . . Jan., Safety lessons from nature . . . Feb., Accident reports and their use . . . March, Bicycle riding . . . April, Spring games . . . May, Vacation safety.

A group of accident and safety articles in *Red Cross Courier*, Washington, D. C. Dec., 1937. Includes review of recent progress in rural extension of first aid.

In the 21st volume is *California Safety News*, the little quarterly issued by Industrial Accident Commission, State Bldg., San Francisco, Calif. A feature of the Dec., 1937, issue is a group of case stories: "Another Scaffold Accident" . . . "Broken Grindstone" . . . "Did He Think?" . . . "Who Was Responsible?" These and other stories appear under the general heading across two pages: "These Accidents Were Caused, They Did Not Merely Happen."

"Quick! Henrietta, the Iodine!" is the title of an article on accident emergencies in the home. *Health*, 105 Bond St., Toronto, Ont. Dec., 1937. 15 cents.

The National Safety Council reports 106,000 fatal accidents in 1937, with 15 per cent decrease for the year in

the home, 5 per cent decrease in public (non-traffic), 6 per cent increase in occupational, and 4 per cent increase in traffic deaths.

Aetna Affiliated offers "How Good a Driver Are You?" "Check Yourself by taking this safe driving examination." One of the popular self-scoring devices which the alert safety worker can get into use in groups as well as by individuals.

The Committee on Accident Prevention, Canadian Public Health Assn., recommends that—

Nonofficial local agencies engaged in the education of the public in connection with traffic safety should be encouraged to make use of the services of municipal health departments when planning safety campaigns.

"Guides to Traffic Safety," prepared by Executive Committee of National Conference on Street and Highway Safety, is published by Bureau of Public Roads, U. S. Dept. of Agriculture. Seems particularly helpful to health workers as a general review of the field. There are sections on education, school, and general public. Supt. of Documents, Washington, D. C. 10 cents.

Home accidents, safe driving, home and community fire hazards are treated in educational material from Aetna Affiliated Companies, Hartford, Conn. Especially interesting is "Let's Be Skillful" with 10 good sized page diagrams of street hazards. (Not quite so clear as they could have been if appearance had been neglected slightly for effect.) These pages suggest their reproduction on bulletin boards, or for school use. In home or school similar problems might be worked out with cut-out pictures of automobiles.

National Fire Protection Assn., 60 Batterymarch St., Boston, Mass., is a source for educational plans and materials for use in schools or elsewhere. "Fire Prevention I.Q." is a 4 page folder; 25 questions, each with 4 or 5 possible answers, the correct answers

on the 4th page. Rotary and other luncheon clubs would be interested in getting copies (100 for 50 cents) to test their members at the weekly meeting. Samples free.

"A Pictorial Story of the American Highway" includes a group of scenes to illustrate the statement of the National Safety Council that in many instances the billboard "seriously distracts the attention at such critical locations as underpasses, grade crossings, and abrupt hill crests." In *Roadside Bulletin*, National Roadside Council, 119 E. 19th St., New York, N. Y.

"The Psychology of Accident Causation and Prevention," by H. M. Vernon, M.D. *Trained Nurse and Hospital Review*, 468 4th Ave., New York, N. Y. Oct., 1937. 20 cents. Accident-proneness and treatment, child suggestion susceptibility in accident prevention.

A surprisingly simple idea for safety education in a small shop is described under "A New Idea In Safety Programs" in *The Foreman*, Employers Mutuals, Wausau, Wis. Nov.-Dec., 1937. In brief, every employee in turn is Safety Marshal for a day. His first duty is to write a 10 to 20 word safety message (warning, reminder, or factual statement) which is posted in a frame where all workers may see it. His second duty is to appoint the Safety Marshal for the next day. The reproduction of one of the messages in its display holder emphasizes the hopefulness of the idea. It might be tried in offices, schools, etc.

A 2 page bulletin on "Special Winter Hazards," Employers Mutuals, Wausau, Wis., mentions slippery walks . . . falling on icy ground (how to fall without injury) . . . frostbite . . . snow on roofs . . . icicles . . . cranking . . . carbon monoxide poisoning . . . and gives bad weather driving hints and how to thaw frozen pipes.

What about safety? This question is raised as the conclusion of "Auto-

mobiles of 1938," by D. H. Palmer, *New Republic*, 40 E. 49th St., New York, N. Y. Jan. 5, 1938. 15 cents. The article reviews the varied improvements and so-called improvements. Almost anything man may think of is there—except durability, economy, and safety.

STAFF TRAINING

"Community Health Education" is one course announced for the 1938 summer session for public health nurses, University of Kentucky, Lexington, Ky. First term, June 13 to July 16.

"School of Hygiene and Physical Education." Reprint from annual report of the President. Stanford University, Calif. Free. About Division of Informational Hygiene, Division of Physical Education Activities, Men Students' Health Service, University Health Service, etc.

"Selection and Training of Nurses by a State Health Department," by L. M. Blaisdel. New York State Dept. of Health, Albany, N. Y. Reprint. Free.

"Tuberculosis: A list of free and inexpensive materials." *American Journal of Nursing*, 50 W. 50th St., New York, N. Y. Dec., 1937. 35 cents.

"What Does the Student of Institutions for the Education of Teachers Know about Eye Health?" by A. M. Phelan. *Sight Saving Review*, 50 W. 50th St., New York, N. Y. June, 1937. 50 cents. Reprint for 10 cents.

Up in Buffalo it was that 70 or more public health nurses attended the first Institute on Health Education and Interpretation of Public Health Nursing Services conducted by the New York State Dept. of Health. The meeting was planned by Florence Manley, R.N., District Supervising Nurse, and Ethel Hendriksen, Field Agent of the Division of Public Health Education.

The primary purpose of the Institute was to bring about better understanding of the health objectives of lay organizations, such as home bureaus and 4-H clubs, and to demonstrate how guidance by the health officer and the public health nurse is welcomed by these agencies. By careful study of health education methods it is hoped that nurses may make their services in this field more effective.

The discussion centered about the public health nurse and her part in health education, and the community and its resources for health education.

Commonly used technics were presented: radio, newspaper releases, public addresses, reports, and community organization.

MAGAZINE ARTICLES

Articles to read, to quote, to mention in bulletins, to write letters about.

In one year *Look* has reached 2 million circulation and *Life* in 14 months has reached 2 million a week. Possibly we should study both *Life* and *Look* to seek some understanding of the different audiences.

Here is another: *Picture*, 350 E. 22d St., Chicago, Ill. Monthly. 10 cents. One of the better grade of picture magazines; goes for the "picture essay" form, as it is known to *Life*. In March, 1938, are 4 pages on "How Should You Tell Your Child about Sex?" prepared with coöperation of American Social Hygiene Assn. The opening is a page picture thus captioned:

"Why Is Bobby Different?" Brothers and sisters enjoy an immense advantage over the "only child." When Betty and Bobby swim together they notice the differences in their bodies in the same way that they observe anything that seems unusual to them . . . And they will want to know "Why?" Wise parents explain that boys and girls are formed differently so that they may later become fathers and mothers.

In the same issue of *Picture*: "Diagnosis While You Wait." 4 pages emphasizing, not horribly, that

"This marvelous 'frozen section' method saves lives every day. Suspected cancer

tissue is diagnosed during operations. The surgeon has his answer in 5 minutes."

"And Now, a Co-op Hospital," by A. D. Carlson. (Elk City, Okla.). *Survey Graphic*, 112 E. 19th St., New York, N. Y. Sept., 1937. 30 cents.

"Crippled in the Tongue," by A. D. Carlson. *Harpers*, 49 E. 33d St., New York, N. Y. Oct., 1937. 40 cents. Speech defectives.

"Home, Lethal Home," by R. E. Vernor. *Rotarian*, 35 E. Wacker Drive, Chicago, Ill. Jan., 1938. 25 cents.

"It's startling but true! You're safer"—statistically speaking—dodging highway traffic than in the bosom of your own household.

"How Fast Can You Stop Your Car to Avoid Hitting a Child?" Two pages of pictures showing how "Jerry," a wooden dummy of a boy on roller skates, and an "electric eye" check a driver's reaction in the face of actual accident causes. *Look*, Des Moines, Ia. Feb. 15, 1938. 10 cents.

The *Ladies Home Journal* has joined the tabulators of "public opinion." The Feb., 1938, issue reports that the women of America believe:

"That young people should be taught more about sex before they get married."

"That sex instruction should be given by their parents."

"Minds That Come Back," by J. D. Ratcliff. *Collier's*. Feb. 12, 1938.

"Insulin shock, the new, violent method of dealing with certain forms of insanity, is as dramatic as medieval magic. And it really works. Dr. Manfred Sakel, its inventor, has brought hope to hundreds of thousands of persons otherwise condemned to a life of constant nightmare."

"Night Call," by W. Martin. *Collier's*. Dec. 25, 1937. "Story of a young doctor whose heart and courage were greater than he knew."

"Now They Are Ahead of the Public," by Douglass W. Orr, M.D. and Jean W. Orr. *Survey Graphic*, New

York, N. Y. Feb., 1938. 30 cents. "The changed front of the British medical profession toward health insurance." What the medical secretary of the British Medical Assn. says.

"Pneumonia Mortality May Be Cut in Half by Use of New Serums." 5 pages of pictures with text. Includes portraits of Dr. Parran and Dr. Rice. *Life*, 330 E. 22d St., Chicago, Ill. Dec. 20, 1937.

"Preying Guests," by Dr. V. G. Heiser. *Collier's*. Jan. 15, 1938.

"The way parasites behave is an open scandal, but nobody can call them dumb. . . . Dr. Heiser describes their adventurous careers and the means at our disposal for stopping them."

"The Student Nurse Prepares for an Arduous But Noble Profession" at Roosevelt Hospital School of Nursing she studies, has fun, cares for the sick. Eight pages of pictures, and cover picture. Practically none of those in the pictures are looking at the camera, and the reader. Text emphasizes the professional training, and the desirable personal characteristics. *Life*, Chicago, Ill. Jan. 31, 1938.

"Traveler's Aid," by Dr. V. G. Heiser. *Collier's*. Jan. 1, 1938.

"If you are going to get any good out of your trip you have to stay well . . . Dr. Heiser, who has spent his life traveling, tells you what to look out for."

"The Unhappy Drinker," by F. T. Chambers, Jr. *Saturday Evening Post*. Jan. 15, 1938. Tells of "the key to the behavior of the unhappy drinker," and explains that

Neither the novice nor the seasoned alcoholic can be helped by emotional appeals or by threats of punishment—as families of drunkards would do well to learn. The problem must be faced in a scientific, matter-of-fact manner, with no more moral judgment brought into play than if the patient were suffering from typhoid fever or a broken leg. The alcoholic is already emotionally unbalanced, and appeals to his better nature

are as useless as appeals to the logic of a man who is insane.

If the abnormal drinker is treated as a medical case, suffering from a common form of mental illness, little damage is wrought his self-respect, and results are more rapidly obtained. . . .

"What 19,000 Doctors Could Tell Us," by Douglass W. Orr, M.D. and Jean W. Orr. *Survey Graphic*, New York, N. Y. Dec., 1937. 50 cents.

"Dr. and Mrs. Orr have made the first intimate study ever attempted of how wage earning families no less than panel doctors feel about the health insurance system that Britain inaugurated 25 years ago."

"The Workers Say, 'Yes—and More,'" by Dr. D. W. Orr, and Jean W. Orr. *Survey Graphic*, New York, N. Y. Jan., 1938. 30 cents. British wage earners want more of sickness insurance.

MOTION PICTURES

A 1937 revision of "Medical and Dental Films" is available through Bell and Howell Co., 1801 Larchmont Ave., Chicago, Ill. 73 mimeographed pages. 50 cents. List of available professional and popular 16mm. films on medical, surgical, health hygiene, and dental subjects. Includes psychology, biology and allied subjects of professional interest. The strictly health pictures are limited in number. A chapter on "Making Medical Movies."

Aetna Life Affiliated Companies, Hartford, Conn., offer films and slides on safety topics for free use.

Highway safety: "Saving Seconds" . . . "The Truck and the Driver" . . . "Let's Be Skillful" ("There's no fun being a dub!") . . . "How to Park Your Car."

Fire prevention: "The Bad Master" . . . "Sounding the Alarm."

Home accidents: "Sentinels of Safety."

If you wish to check the use of motion pictures in exposition or fair exhibits see "Behind the Screens at the Century of Progress." Reports on the practice of exhibitors as to silent

and talking pictures, amateur and professional, space required, how projector was placed, when chairs are needed, about continuous operation, size of screen, etc., together with a machine manufacturer's arguments for the use of pictures. Bell and Howell Co., 1801 Larchmont Ave., Chicago, Ill. Free.

"Social Service and the Films," by Dee Lowrance. *Better Times*, 44 E. 23d St., New York, N. Y. Feb. 7, 1938. 35 cents. A review of the commercial production of social films, the attitudes of producers, the *March of Time's* presentation of health and other social themes, the documentary films being made in England and the situation in this country. Of interest to health workers as background on health movie production.

"The Why and How of Titles," by J. W. Moore. *Movie Makers*, 420 Lexington Ave., New York, N. Y. Feb., 1938. 25 cents. Crowded with ideas on when, what, and how. (Other usable material, of course, in the same issue.)

"Without doubt," says Michigan Tuberculosis Assn.:

"... talking pictures have been the means of interesting many people in tuberculosis. Clearly explaining the importance of the tuberculin test and diagnostic chest X-ray in discovering tuberculosis early, the motion picture program is an invaluable phase of the Association's constant health education campaign. To build up a far-reaching movie program is the aim of the association. During the coming school months, showings will be concentrated in lower Michigan. "Contacts" and "Behind the Shadows" will be presented before as many schools as possible."

"Behind the Shadows" is the first sound movie produced by the National Tuberculosis Association. The same picture has been made with titles for use without sound. Both versions are available in 35mm. and 16mm., both on safety film. One reel.

"The photography is of the best; it was done in an eastern studio under the direction

of Hollywood-trained experts. Hospital and medical scenes were checked for authenticity by two physicians while the photography was in process. The animated diagrams were executed by the staff illustrator of the Presbyterian Hospital in New York, who is master of animated diagram technic. The sound effects are perfect—good diction, clear enunciation."

NEW

Here's Health is a mimeographed news sheet to supplement *Delaware Health News*, the printed bulletin. State Board of Health, Dover, Del. Part of a news release announcing the first issue follows.

Under the title "Here's Health" the State Board of Health has commenced the publication of a mimeographed house organ, to be sent to board members, staff and interested associates, with the announced purpose of more firmly welding together the workers through keeping each informed of the programs, activities, and problems of the others.

An outline drawing of the State of Delaware and its counties, with small circles indicating the principal communities, acts as a background for the text of the first page, while the title, "Here's Health!" in half-inch letters, occupies the upper right corner. In ordinary publications this outline map will serve to set off the text, but it will be possible to use it for purposes of statistical indication, by typing-in the names of towns or counties, or by indicating them with different markings.

DATES AHEAD

Health agencies generally may make some use of special days, even outside of their own special fields. To remember a special day on the office bulletin board, in a staff meeting, or in the staff house organ will be at least a minor contribution to broader staff interests. Worth while, is it not?

It was in March, 1877, that the first visiting nurse started her rounds.

St. Patrick's Day, March 17, may well be made a peg upon which to hang a health editorial—if suggested to a sympathetic editorial writer.

The first day of spring. March 21,

should tempt some special news releases. How about the "sulphur and molasses" of by-gone days?

And April 1 is the day for remembering the greatest of them all, the health fool!

National Negro Health Week, April 3-10, 1938. Plans are outlined in *National Negro Health News*, U. S. Public Health Service, Washington, D. C. Send early request for samples of bulletin, poster, and school leaflet.

Daylight Saving, in many communities, starts the morning of April 24.

National Garden Week, National Boys' and Girls' Week, and National Better Homes Week usually come in April, but no 1938 announcements have been noted.

May Day is not far off. We have heard of no national planning, but doubtless some states and many cities will initiate plans for a Health Day.

"National Hospital Day," May 12, is also "Florence Nightingale Day." What several cities did a year ago is reported in *Hospitals*, 18 E. Division St., Chicago, Ill. Feb., 1938.

A "Drive Safely" poster contest closes April 29, 1938. Prizes of \$10 up to \$1,000, are offered by Devoe and Raynolds Co., 1 W. 47th St., New York, N. Y., who will send the simple instructions. The "problem" as stated:

To create a poster so dramatic and compelling that it will induce motorists to drive safely—thus reducing the annual toll of accidents in this country which bring sudden deaths to thousands of persons and cause many more thousands each year to live on in the nightmare of mangled flesh and bones.

Money and fame await the artist who can most successfully create such a poster. And to that artist, thousands of persons including, perhaps, members of his own family, will owe their lives!

Early Diagnosis Campaign for 1938 will soon be on. "Uncover Tuberculosis by Modern Methods: 30 Years of Health Education." An 8 large page

pamphlet; tells "Why," "When," "Where," to campaign, "Who" to reach, and "How" to go about it. A striking pyramid emphasizes the audiences and the job to be done. The materials described include pamphlets, posters, talks, newspaper copy, a new movie, exhibits, and several forms of direct national aid. Get copy from some tuberculosis association.

REPORTING

A diagram of activities is included in the annual report of Massachusetts Society for Mental Hygiene, 3 Joy St., Boston, Mass. Simply made, it gives a quick review of what the Society was doing last year.

"Guarding the Health of Kern County" appears in the center of the cover-page and the title-page of the annual report of Kern County Dept. of Public Health, Bakersfield, Calif. *There is a detailed table of contents. There is a page on "Activities in Public Health Education."* There are 3 pages reporting on the coöperating agencies, public and private. There are nearly 2 pages of comment by Health Officer Smith, partly buried as "Conclusions" at the end of the report. This material was worth moving to the front part of the book, and then setting it in larger and more readable type.

Again "Guarding the Health of Baltimore" appears on the blue bound pamphlet which contains "A reprint from the annual report of the City Health Department." Two pages tell about health education. Back of the title page appears this quotation from Governor William Bradford's History of Plimmoth Plantation:

"Out of small beginnings greater things have been produced by his hand that made all things of nothing, and gives being to all things that are."

New Haven's Dept. of Health annual report *has a table of contents.* The title page carries an upright bar

diagram of New Haven's health dollar. We will tell more about the page and a half on public health instruction next month.

On the cover a lighted candle, and these words: "How far that little candle throws its beams! So Shines a Good Deed. . . ." On the title page: "A Decade of Sight Saving: 1927-1937. The Illinois Society for the Prevention of Blindness" (203 N. Wabash Ave., Chicago, Ill.) Inside is a narrative account of the 10 years, with open readable pages, which will not be read through quite as generally, or be remembered as fully, as would have followed the addition of sub-headings.

Here is a new proposition as to publication of reports: All concerned with rehabilitation of the tuberculous know about the Altro Work Shop, which is a major undertaking of Committee for Care of Jewish Tuberculous, 71 W. 47th St., New York, N. Y. Executive Edward Hochhauser announces a comprehensive report of the committee and the 22 years of the Shop; about 80 pages, including contributions by Dr. Kendall Emerson and Louis I. Dublin, photographs and charts. Copies available if ordered in advance. *35 cents, paper; 55 cents, in cloth.*

IN BULLETINS AND JOURNALS

The most unusual health journal of the month was the Dec., 1937, issue of *Journal of Social Hygiene*, 50 W. 50th St., New York, N. Y. This issue was devoted solely to the 25th anniversary dinner of the American Social Hygiene Association, an event in honor of Dr. William Freeman Snow. There are many pages of addresses, and of messages from those who could not be present.

"Public Health and Social Work" is a new heading under "Books and Periodicals" in the monthly issues of *Journal of Home Economics*, Mills Bldg., Washington, D. C.

Understanding the Child, National Committee for Mental Hygiene, 50 W. 50th St., New York, N. Y., seeks to give atmosphere and information introductory to each of its articles. Usually there is a one column cut of the author. Across the 2 column page is a paragraph about the author and the article. Under "With Our Contributors" are grouped personal notes about some of the authors.

"A Year of Best Records . . . 1937 a Star Health Year" according to *Statistical Bulletin*, Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y. Jan., 1938. *Free*.

Too many capital letters make needlessly difficult the reading of *National Negro Health News*. This difficulty carries over even to the display pages where every word starts with a capital. With capital for first word of a line the whole would look better and read better.

"Book and Pamphlet Notices" is a useful section of *Ohio Public Health*, Ohio Public Health Assn., 1575 Neil Ave., Columbus, Ohio.

"The Doctor's Reply." *Weekly Bulletin*, Municipal Dept. of Health, Albany, N. Y. Dec. 30, 1937. "Doctor, can you cure me?" as answered by Drs. Charlatan, Cocksure, Play-for-time, Pseudo-Honest, Foolishly Honest, Cruelly Honest, and Sensibly Honest.

Health Habits, Iowa Tuberculosis Assn., Flynn Bldg., Des Moines, issued for teachers, is pleasing to the eye because of the substantial light green paper.

Memphis Health Bulletin, Memphis, Dept. of Health, carries a table of contents on the inside cover page.

N. J. T. L. News, weekly mimeographed bulletin of the New Jersey Tuberculosis League, 15 E. Kinney St., Newark) impresses one with the weekly

record of extensive and varied health activity in a populous state. The persistent way of the League in supplying, week by week, ready made copy for local use ought to bring educational material into many periodicals throughout the state. Almost all of this material is submitted with suggestions for local adaptation. We hope to receive a report on the extent of actual local use.

This Job of Ours, bearing signature of Health Commissioner John L. Rice, is a weekly, one page sheet, going to the 2,500 employees of the New York City Dept. of Health.

The Nov. 22, 1937, issue began with this paragraph:

A SILVER LOVING CUP was awarded to the Department last month. It was presented by Namm's Department Store for a window display prepared by the Bureau of Health Education with the assistance of the Chemical Laboratory. As part of the celebration of Brooklyn Day, Namm's gave window space for exhibits explaining the work of the various city departments. The Health Department's exhibit which dealt with the protection of food was seen by thousands. The preparation of exhibits is but one part of the work of the Bureau of Health Education.

Then followed 4 paragraphs telling more about the educational contact of the department with the public, and with professional groups.

"Why Children Die?" in *Birmingham's Health*, Birmingham, Ala., Sept., 1937) is followed by two pages on "The Leading Causes of Death in the Younger Age Groups in Jefferson County." "Under one year," and 7 other periods are given, and for each are the percentages of total deaths for the 4 chief causes of death in the period; at the left a cut of four horse-men of death, at the right a silhouette of a child of the respective age period.

BOOKS AND REPORTS

Annual Report of the Surgeon General, Public Health Service of the United States—*Fiscal Year Ended June 30, 1937*. Washington: United States Government Printing Office, 1937. 164 pp. Price, \$.60.

This *Report* is so succinct that a review is somewhat difficult. Only a few of the high points can be mentioned.

Some changes have taken place in the administration. During the year, five offices: Child Hygiene, Milk Investigations, Stream Pollution, Public Health Methods, and Statistical Investigations, which have heretofore operated as separate units in the Division of Scientific Research were merged to form the Division of Public Health Methods in the National Institute of Health.

The Division of Mental Hygiene has completed its 7th full year. Its chief work has been the study of the nature and treatment of drug addiction, carried out largely at the Narcotic Farm, Lexington, Ky.

During the year a plan of "Radio Pratique" was evolved by means of which ships have been able to proceed to dock without stopping at quarantine anchorage and without being subjected to quarantine inspection prior to entering a United States port.

Cholera remains limited to southern Asia and adjacent islands with a high incidence in India, French India, French Indochina, and Siam. Plague was of widespread distribution and attained high incidence in the Far East, in Ceylon, India, and Dutch East Indies; in Africa, as evidenced by reports from Kenya, Uganda, Union of South Africa, and Mada-

gascar; in South America, as reported in Brazil, Peru, Ecuador, and Argentina. Yellow fever appeared to be limited mainly to Africa and South America.

In the scientific work one of the most interesting things has been the continued study of hemolytic streptococcus diseases. A method of purifying and precipitating the erythrogenic toxin of the scarlet fever streptococcus has been developed. The use of such material for active immunization against scarlet fever greatly reduces the objectionable reactions and at the same time increases its immunizing properties. The practicability of the method has been tested in a group involving over 10,000 persons, 85 per cent of whom were susceptible grammar school children and were protected.

The publications of the department have been continued, but it has been found necessary on account of finances to cut the number of pages from an average of 3,000 to 1,700. Many reprints and supplements have, however, been issued, and during the year a new publication called "The Health Officer" has been put out as an experiment in public health education. In spite of the fact that no effort has been made to increase the circulation it has practically doubled.

The Division of Venereal Diseases has been, as might be expected under Surgeon General Parran, active. The American Society of Clinical Pathologists with the Service, has sponsored a project for determining the reliability of serodiagnostic tests for syphilis originated by American serologists, and also the efficiency of state and local laboratories in performing such tests.

In general it was found that the tests are reliable and in most state laboratories the performance of the tests is entirely satisfactory.

Altogether, this report is exceedingly interesting and valuable. It is the story of the work being carried on by what we have often said is the largest and best trained body of public health workers in the world.

MAZŸCK P. RAVENEL

Esperimenti Di Vaccinazione Antituberculare—*Carried out under the Control of the Committee Technical-Scientific, of the Institute for Anti-tuberculous Vaccination. From the Laboratory of Comparative Pathology of the Royal University and Institute for Anti-tuberculous Vaccination of Milan. Director: Prof. A. Ascoli.*

In the English summary of this Report are given the results of the experiments in the use of immunizing products against tuberculosis in calves.

The experiments were carried out on 94 calves, and two tests for immunity were employed: (1) by injection of virulent bovine bacilli, (2) by exposing the treated calves to animals suffering from open pulmonary tuberculosis, thus establishing a sure source of natural infection.

It appears that the use of live bacilli gave excellent results in immunizing calves against both fatal doses of virulent tuberculous infection and natural exposure to the disease, and that no other form of vaccination, such as the dead heated cultures, is of value in immunization. When large amounts of dead heated cultures were injected in an effort to immunize calves, they not only were not protected but were much more susceptible to subsequent exposure to tuberculosis.

When using living bacilli for immunization unless calves were revaccinated and kept for a certain time

after away from natural contagion the protection was not as marked. Unless precautionary measures are carefully observed, even the use of live bacilli for immunization will fail. In other words the precautionary measures are essential to success in immunization of cattle against tuberculosis.

This research represents painstaking investigation which deserves commendation, but the results are a little difficult to interpret because of the way they are expressed in the translation into English.

The situation in which these researches were carried out is perhaps quite different from those existing in the United States but we believe that in general the effort devoted to tuberculosis could much better be given to eradication such as has been carried out in the United States. With the exception of two states, the entire United States at present has been declared a modified accredited area for bovine tuberculosis, which means that in such areas there exists less than one-half of 1 per cent of the disease in cattle.

A. J. DURANT

The Cost of Adequate Medical Care—*By Samuel Bradbury, M.D. Chicago: University of Chicago Press, 1937. 83 pp. Price, \$1.00.*

Much has been said and a great deal written about the cost of medical care and of the inequality of distribution of medical service for the people of the United States. There has been some confusion, however, as to the actual cost of adequate medical care.

This book, written by a practising Philadelphia physician, presents in 12 chapters, 13 important tables, and 9 indices, an interesting picture of what these actual costs are, based upon studies of schedules of fees charged by general practitioners, surgeons, specialists, hospital laboratories, etc.

Chapters are devoted to the ex-

pectancy of illness, to the type of practitioner and kind of service required and the cost for the individual and family for the treatment of certain specific diseases thoroughly analyzed. Good medical care is properly defined and the principle stressed that medical care of high quality cannot be furnished cheaply.

The amount of fact-finding contained should particularly appeal to the medical profession, administrators, social workers and all who are genuinely interested in the subject of medical economics. CHARLES F. WILINSKY

A Pediatrician in Search of Mental Hygiene—By Bronson Crothers, M.D. New York: Commonwealth Fund, 1937. 271 pp. Price, \$2.00.

But we doubt if he found it! We fear he was searching for the "will-o-the-wisp" and, to boot, quixotically tilting at windmills.

This is a vexatious little book—both because of things it says and those it leaves unsaid. Had the author defined psychiatry *and* mental hygiene he would not have had the need to knock down so many straw men. And also, had he realized that a mental concept does not correspond to any objective reality he would not be looking for the "whole child in a total environment."

In view of the above, one is not surprised that the author can go on for 236 pages and then write, "In the preceding chapters the reader can easily see that the writer has been constantly drawn toward *psychiatry and mental hygiene* (italics mine) and then has withdrawn again and again."

Undoubtedly the author does represent in his thinking many physicians. This may be paraphrastically stated, "That only is scientific which is materialistic hence psychiatry is at best the art of medicine." The reviewer would question both the concepts scientific and psychiatry when so used.

The author states that the pediatrician's primary responsibility is the treatment of the physical ills of childhood, *i.e.*, the diseases due to physical agents. This thought is basic throughout his discussion. But he is not satisfied with just that. He wishes to make growth and development a more meaningful concept. This is what leads to the groping so poignantly expressed in this book. He has come to see that the child when asked may throw light on his dis-ease, and also that it is well worth while taking the time to elicit facts not discoverable on mere physical examination.

In fact, the author is unquestionably doing a nice piece of work at the Children's Hospital of Boston as the chapter, A Teaching Experiment in Action, shows. We are of the opinion, however, that until the day comes when medical students will receive more adequate training in psychopathology and psychotherapy in a more correlated manner than is generally true at present, such attempts at training internes and residents as described by him are at best make-shifts.

Since we agree with some of the strictures against the psychiatrists in extramural work and the propagandists in mental hygiene societies, we would recommend the reading of this book to all such. Medical students and practicing pediatricians need more clearly formulated material if it is to be of value to them. Teaching pediatricians may find consolation in knowing that a fairly good practical job can be done even though they too, together with many an extramural psychiatrist, still may be in search of mental hygiene. HENRY C. SCHUMACHER

The Family in Health and in Illness—By Florence Brown Sherbon, M.D. New York: McGraw-Hill, 1937. 500 pp. Price, \$3.00.

This book was designed as a college

text "to help the young woman student prepare herself for the responsibilities of the family, and incidentally, community life." Its 45 chapters deal with the fundamentals of Family Relationships, Biology, Anatomy, Physiology, Nutrition, Food Chemistry, Public Health, Disease, Bacteriology, Medicine, Nursing, and Emergency Treatments.

The subject matter is presented, not for the technically trained student of medicine, nursing, or dietetics, but for the home maker who has had training in the basic sciences and in Home Economics. Special attention is given to prevention of disease and of accidents; emergency treatments; improvised equipment for nursing; and to entertainment and occupation of the sick. Sick room procedures are presented in a way to enable the home maker to carry out the physician's orders in a scientific and safe manner.

The strongest feature of the book is the excellent manner in which it is illustrated, having 200 figures in all, including diagrammatic drawings, charts, and photographs. These both clarify and create interest in the subject matter. The list of good references at the end of each chapter should be helpful to both teacher and student; and the clear, concise definitions of the new technical terms at the beginning of each chapter would be a great help to the student.

As far as subject matter is concerned, there seems to be very little presented that is really new in any of the many fields discussed. I find nothing whatever new in the chapters dealing with food needs, chemistry of foods, minerals, vitamins, diets, feeding the sick, and emergency treatments. Also, instead of selecting a few important facts and expressing them in simple, concise style, there is some poorly chosen material. For instance

in the chapter on "Food Needs," the author does not show *through what articles of diet* the needs of the body, as presented, may be satisfied; likewise, in the chapter on "Feeding the Sick," and in the one on "The Chemistry of Foods," *no principles of food preparation are stated*. It seems also that more material, not too technical could have been included on *diet* in disease, if this book is to be used by home economics trained home makers.

In the chapters dealing with nutrition, some loose statements, often misleading or confusing are made, such as in Chapter VIII, "a safe, practical rule for the active person in normal health is to eat meat *not over once daily*"; in Chapter IX, "potassium combining with the sodium in such a way as to remove it from the body," and "thyroid, is devoted exclusively to the regulation of iodine metabolism." Similar quotations might be taken from Chapter X.

In spite of these criticisms, *The Family in Health and in Illness* is without question the best book which has been written for use as a textbook for college courses in home care of the sick, and it certainly fills a long felt need in home economics work.

JESSIE ALICE CLINE

**Health Education of the Public:
A Practical Manual of Technic—
By W. W. Bauer, M.D., and Thomas
G. Hull, Ph.D. Philadelphia: Saun-
ders. 227 pp. Price, \$2.50.**

"Out of the experiences of many workers there has grown up a formidable mass of knowledge and experience. It is now possible to state with considerable definiteness what are the functions, the purposes, the advantages, the disadvantages of the several media which are available to the health educator." The aim of this text is to expound these potentialities in a field of education, and of health, that has been little understood, little emphasized, and usually poorly taught. Most "health educators," like Topsy, have "just growed."

The text starts with a chapter on "Definitions and Objectives." This lays the foundation for succeeding chapters on such topics as source of materials, means—for example the radio, exhibits, meetings, pamphlets, newspapers, motion pictures, and other devices and aids to publicity.

Just as the poor teacher under criticism told his high school principal that "he could teach them all night if he could get them to listen," so the major problem of the health educator is to "get them to listen."

This text presents a world of suggestions as to material and methods. It will be of great aid to those responsible for spreading the gospel of health—continually and almost continuously threatened with smothering by the noxious waves of misinformation put out by advertisers through the same media as suggested in this splendid discussion.

It seems to be a case of "fighting fire with fire." Any teacher is faced with three basic questions, upon the proper answering of which the satisfactory solution of his problem depends: whom am I going to teach? What am I going to teach? How am I going to teach? This text places before us the means of answering "what" and "how."

CHARLES H. KEENE

Your Diet and Your Health—By Morris Fishbein, M.D. New York: McGraw-Hill, 1937. 298 pp. Price, \$2.50.

With his usual clarity and felicity of expression, Dr. Fishbein has written an interesting and instructive book on diet for the general reader. In it he presents in popular language the latest authentic facts about the newer knowledge of nutrition, debunks the weird theories of some of the more blatant faddists, and discusses such pregnant topics as reducing, food sensitivities,

and diets in disease conditions, although the last is necessarily somewhat sketchy. Special chapters are devoted to the more important food categories, milk and its products, bread, meat, fish, vegetables, and fruits. An appendix gives valuable data on foods and diets, and there is a good index. This book should serve a useful purpose in helping to inform the public about the essential rôle of diet in the promotion and maintenance of good health. For that purpose it can be highly recommended.

JAMES A. TOBEY

New Light on Delinquency and Its Treatment—By William Healy, M.D., and Augusta F. Bronner, Ph.D. New Haven: Yale University Press, 1936. 226 pp. Price, \$2.00.

Again we are indebted to the authors of this book, for an outstanding contribution to the understanding and treatment of varying problems relative to delinquency.

The basis of this study is a long-term critical analysis of factors making for and against delinquency tendencies and behavior in 105 delinquents compared with 105 children controls belonging to the same family. Of particular interest is a discriminating study of 8 pairs of twins, one of each pair in each instance being a delinquent. The study of this unique material has led the authors to formulate their pivotal conclusion: that the nucleus of delinquent behavior is symptomatic of profound emotional disturbance ingrained by virtue of early life experiences in the life of the delinquent child.

The value of the book is enhanced by the inclusion of representative case material which clearly illustrates various aspects of the problems of delinquency. Of significance is the emphasis which the authors place upon the importance of prevention in delinquency programs. Substance is given to this hope by supplying methodology which

goes with factual material to justify conclusions and generalizations.

The contents are concerned with chapters upon new orientations and the significance of delinquency, introduction to research, the significance of taking the family instead of the delinquent as the unit of research, comparison of emotional experiences of delinquency versus controls, treatment program together with outcomes and new orientation for treatment and their correlations, and, finally, some practical implications of this particular research.

These pioneers and leaders in the field of delinquency have made a most significant contribution in this research which was intended for the Institute of Human Relations of Yale University. Teachers, social workers, juvenile court judges, probation officers, psychiatrists, and all professional lay persons desiring a fundamental grasp of up-to-date conceptions and methodology of delinquency can do no better than to read this timely contribution.

FREDERICK L. PATRY

A Handbook of Accepted Remedies—*Edited by P. J. Hanzlik, M.D. (2nd ed.). San Francisco, Calif.: Department of Public Health. Published by J. W. Stacey, Inc., 1937. 115 pp. Price, \$1.50.*

The first edition of this exceptionally good handbook was rapidly exhausted. The second edition has been brought up to date and maintains the high standard set by the first. A number of new items have been added. Like the first edition, this can be highly recommended in its field.

MAZÛCK P. RAVENEL

Maternal Deaths: The Ways to Prevention—*By Iago Galdston, M.D. New York: Commonwealth Fund, 1937. 115 pp. Price, \$.75 cloth, \$.50 paper.* Dr. Galdston has performed a valu-

able public service in bringing together and reducing to words of one and two syllables the mass of data gathered during recent years on the controversial subject of maternal mortality. He has clothed the subject in non-technical language. Brevity, clarity, and authenticity characterize the book. In this concise form it is readily understandable by the laity. It has a place also in the hands of social workers, nurses, hospital administrators, and all others engaged in public health work.

The book should lead to individual and community action to put an end to the reprehensible maternal morbidity and mortality in this country. The author succinctly states in the foreword that—

Maternal mortality and morbidity cannot be materially reduced by the efforts of the medical profession alone. The problem must be understood and a solution sought by every individual and every organization interested in public health and in public welfare.

Chapters on the preventable deaths, prenatal care, the attendant at delivery, midwife practice, place of delivery, operative versus spontaneous delivery, Caesarean section, abortion, etc., appear in logical sequence. The concluding chapter on what can be done about it is especially practical and helpful. An appendix is devoted to a consideration of the community organization in Cleveland for obstetrical service in hospitals and the antepartum group instruction to mothers sponsored by the Cleveland Academy of Medicine and the Child Health Association.

RICHARD A. BOLT

Diseases of the Nervous System in Infancy, Childhood and Adolescence—*By Frank R. Ford, M.D. Baltimore: Thomas, 1937. 953 pp. Price, \$8.50.*

Fairness to this opus cannot be given by means of an all-inclusive summary.

It has become necessary to consider each portion separately in the form of a chapter review.

In chapter I, three major divisions have been chosen: nervous diseases due to: (1) Congenital origin, including birth injuries and prenatal defects of development; (2) Those of acute onset—chiefly the encephalitides; (3) Insidious, slow onset—heredo-degenerative diseases, chronic infectious processes and most brain tumors, disturbances of the sympathetic-autonomic system, including: sweating, salivation, disturbances of visceral innervation and vasomotor conditions. This chapter ends with a discussion of the advances in the last ten years in the testing of the autonomic system.

The heading of Chapter II, *Clinical Aspects of the Anatomy and Physiology of the Nervous System*, immediately attracts attention. The opening paragraph says that here is something different. The detailed anatomy and development are to be relegated to the proper textbooks. These will be described only as need be to clarify aspects of clinical importance. The embryological development and function of the nervous system is described with the clarifying use of Dr. Meyer's terminology of "segmental apparatus" and "suprasegmental structures."

The ten pages devoted to the anatomical consideration of the arterio-venous system are worth more through condensation than many times more pages in some anatomy texts.

Prenatal Diseases of the Nervous System are conveniently divided in Chapter III. Those due to absence or incomplete formation and those diseases in which the nervous system has developed to a certain point at which there has been a destruction of the nervous tissue. The author endeavors to point out the difficult differentiation between these diseases and the heredo-degenerative diseases: he further elabo-

rates this differentiation in the following chapter. The insidious, progressive nature of the latter is stressed. In distinguishing these he says that generally the evidence of morbid heredity is not nearly so convincing as in the progressive degenerations. The classification offered is based upon defects of anatomical development. Briefly these are: defects due to closure of midline structures (cerebral and spinal cord), absences and defects of centers, neurons, ganglia and hypertrophies.

It should be said that in Chapter V, on *Infections and Parasitic Invasions of the Nervous System*, as throughout the book, can be seen a conservative yet a thoroughly critical view. This can better be judged by reading the compact condensation of the recent and voluminous literature which is presented. One can see in subject after subject the crystalline substance of innumerable authoritative works. It should be emphasized that time and again a topic has been presented as adequately in a short space as could be gotten from laborious search through many journals and texts. This should more than appeal to the physician who wants to know what the disease may be and also wants to know more about it. He will be able to find just that in this book. The author does not agree with certain European writers "that it is justifiable to attribute congenital defects of the nervous system to syphilis, unless there are serological or other evidences of the active disease."

Chapter IX is titled *Injuries of the Nervous System by Physical Agents*. The most important are the birth injuries. Pressure phenomena due to bony malformations are considered. Finally are included the rarer but interesting effects of radium, roentgen rays, lightning and electric shock and intense sunlight. The discussion of cerebral birth injuries is particularly interesting because of the great amount

of the author's personal experience which is represented. Breech deliveries and prematures show especially high incidence for injuries.

In his concluding chapter the author considers clinical findings; he groups the signs in such a way that the etiology is suggested. We find hemiplegias which may be of congenital origin, those caused by birth injuries, acute infectious diseases, primary infections of the brain, neoplasms, degenerative conditions—each one suggestive in view of the history. Muscular atrophies, spasticities, ataxias, involuntary movements, pain and disorders of sensibility, coma, convulsive phenomena, disorders of speech function, nystagmus, disturbance of behavior are all thus discussed in this final chapter. It is a consummating chapter for which the pediatrician and general practitioner have hoped many years.

Finally a word must be said regarding the well chosen, illustrative photographs, charts, tables, and case histories which do much to make the use of this book a pleasure rather than an "I-suppose-I-should" text. Another feature to be recommended is the position of the bibliography; this will be found immediately following the subject under discussion. In this particular matter a short quotation from the preface will better illustrate a consideration which Dr. Ford has shown throughout the book—"Short bibliographies are appended. In the selection of references, I have favored those which are written in English and which are easily available." Little more need be said for an author who has been chosen by Dr. Brennemann to represent the field of neurology in his "Practise of Pediatrics."

W. F. SCHNEIDER

Board Members' Manual—Prepared by the National Organization for Public Health Nursing, Inc. (2nd ed.)

New York: Macmillan, 1937. 157 pp. Price, \$1.50.

Since 1930 when the *Board Members' Manual* was first published, it has been used extensively as a guide for both administrators and board members of voluntary public health nursing agencies. With the increasing importance in the last few years of the nursing services of official agencies there have developed in many localities lay committees whose purpose is to act as interpretive or advisory committees to these services. For such committees this newly revised *Manual* should also be of real help as it describes the best administrative practice of agencies, giving in brief form such information as every committee member should have. The qualifications of public health nurses for various types of positions, methods of support, the organization of new services, the function of committees in official and private agencies, the use of volunteers, relationships with medical and other professional services, personnel policies—these are but some of the many topics discussed.

New committee members will find this a most helpful guide book. Experienced workers to whom the first edition was well known will find fresh material since the book was completely rewritten by the committee. Health officers and nursing administrators will find the brief discussions and carefully assembled information of real value in their work with lay groups. The reviewer congratulates the N.O.P.H.N. and the Manual Committee on the splendid piece of work which they have accomplished.

KATHARINE FAVILLE

Nutrition: Final Report of the Mixed Committee of the League of Nations on the Relation of Nutrition to Health, Agriculture and Economic Policy. New York: Col-

umbia University Press, 1937. 327 pp. Price, \$2.00.

Among the most valuable and far-reaching activities of the politically impotent League of Nations have been its studies on human nutrition, several of which have been previously reviewed and highly praised in these columns.

This final report of the committee on nutrition, headed by Viscount Astor and including Drs. E. V. McCollum, E. G. Nourse, and Faith Williams, of the United States, consists in part of a brilliant epitome of what is known today about human nutrition and how this knowledge was developed.

Other parts of the report present able discussions of recent trends in food habits throughout the world, with particular reference to consumption, prices, the relation of income and education to nutrition, and the problem of agricultural adaptation to nutritional requirements.

Numerous recommendations for future progress in the improvement of mundane dietetics are a feature of the report. Further scientific study of nutrition problems is urged, and continuous education of professional groups and the general populace in the principles of the optimum diet is advocated.

The report emphasizes the need for the greater use of protective and energy-bearing foods in the daily diet of all persons, recommending that liberal amounts of milk and dairy products, eggs, meat, green and leafy vegetables, fruit, cod liver oil and other fish liver oils be used, along with bread, wheat cereals, and potatoes. The ex-

cessive use of sugar is strongly condemned.

This very well written and attractively printed report should prove of great practical value to all who are concerned in any way with the problem of nutrition and its relation to the health and well-being of the people.

JAMES A. TOBEY

Bacteriology: A Text-Book of Microorganisms — By Fred Wilbur Tanner (3rd ed., rev.). New York: John Wiley, 1937. 510 pp. Price, \$3.50.

This is a third edition which follows the plan of the previous ones. It is designed for general students of academic subjects. An entire chapter is devoted to the nomenclature and classification of bacteria. We have always thought this was a mistake as the whole subject is very far from having been satisfactorily settled, and much of the material constitutes a useless burden on the minds of the beginner.

There is a great deal of practical information in the book on water bacteriology, sewage treatment, bacteriology of milk and milk products, the use of bacteria in the industrial processes in which fermentation is a feature. The chapter on home canning and industrial preservation of foods is interesting and useful.

The book ends with a Glossary which is useful in some respects, but has mistakes. Professor Tanner has large classes and has evidently found the book of use. MAZÛCK P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Available Data about Sludge as Fertilizer—Dried sludge is a practical source of fertilizer and each sewage works operator should popularize its use by florists, farmers, and gardeners. There is much research needed along this line and agricultural experiment stations might well help. These and much else are the conclusions of the A.P.H.A. Committee on Sewage Disposal.

ANON. Committee Report. The Utilization of Sewage Sludge as Fertilizer. *Sewage Works J.* 9, 6:861 (Nov.), 1937.

Call for Action—As a result of conferences between committees of the A.P.H.A. and A.M.A., the Board of Trustees of the latter adopted a resolution urging local medical societies to assume leadership in determining the need for both medical and public health services and to develop procedures for meeting these needs.

ANON. Medical Care for All the People. *J.A.M.A.* 110, 3:212 (Jan. 15), 1938.

Historical Note—Tulare County has its first reported case of tularemia. Looking for plague in 1910, two U. S. Public Health Service Officers ran across a new germ in ground squirrels caught there, which they named *B. tularensis*, because of the location. Later, Francis found "deer fly fever" in Utah to be the result of infection with the same germ; hence he named the disease tularemia. Now the chicken has come home to roost.

ANON. Tulare County Has First Tularemia Case. *Weekly Bull. California State Dept. of Health.* 16, 51:203 (Jan. 15), 1938.

Federal Health Services—Reasons for the establishment of a federal health department are convincingly set forth in this detailed study made by the Bureau of Legal Medicine of the A.M.A. As federal expenditures for health exceed \$100,000,000 annually, it would seem logical that the activities be efficiently organized. If you think so, it would be well to write to the listed committee members to tell them so.

ANON. Why a United States Department of Health. *J.A.M.A.* 110, 4:25B (Jan. 22), 1938.

Nursing Theory and Practice—In theory, the home visit of the public health nurse presents the most promising opportunity to ascertain family health needs and to assist in solving the discovered health problems. The nursing services of three rural counties were reviewed to observe how nearly the nurse's practice approximated these objectives. The conclusion is that the nurses did not render a diversified service in the home visits, so health administrators are invited to examine their nursing programs with a view to attaining these stated objectives.

BEAN, H., and BROCKETT, G. S. The Family as a Unit for Nursing Service. *Pub. Health Rep.* 52, 53:1923 (Dec. 31), 1937.

Typhus, Rats, Mice, et al.—Endemic typhus is increasing in South-eastern United States. A field mouse trapped in Alabama was found infected with the disease, and it is known that 8 other animals, mostly rodents, are susceptible.

BRIGHAM, G. D., and DYER, R. E. Endemic Typhus Fever in Native Rodents. J.A.M.A. 110, 3:180 (Jan. 15), 1938.

Understanding Youth — Mostly about relating local health services to health education in secondary schools, this paper contains much good for teachers and sanitarians alike.

CONNOLLY, M. P. Sources and Uses of Health Material. J. Health & Phys. Ed. 8, 10:596 (Dec.), 1937, and Pub. Health Nurs. 30, 1:22 (Jan.), 1938.

Latest Word about Colds—Virus from patients with influenza is pathogenic for ferrets and can be cultivated in an aerobic medium, whereas virus from patients with colds does not produce an infection in ferrets and can be cultivated only in an anaerobic medium. Immune substances against the influenza virus have been demonstrated, but as yet, protection against colds has failed to materialize. This paper should be studied well.

DOCHEZ, A. R., *et al.* Filtrable Viruses in Infection of the Upper Respiratory Tract. J.A.M.A. 110, 3:177 (Jan. 15), 1938.

Bending the Twig Re Alcohol—Teaching about alcohol and other drugs should be based upon acquaintance with the essentials of growth and bodily functions, which should precede the presentation of effects upon behavior. Personal choice should be based upon education, not duress. Example is important, for teaching without conviction is unsound. It would be difficult to disagree with this excellent paper.

EMERSON, H. Alcohol and Narcotic Drugs. J. Health & Phys. Ed. 8, 10:588 (Dec.), 1937.

It Depends on the Flea—Of the fleas that transmit plague, the rat flea, *cheopsis*, is the one which does the most damage, but the infection kills the flea as quickly as it does rats and men. Some other varieties of fleas, though

they can transmit the disease, do so less easily and themselves survive the infection for longer periods. This seems to account for the slow, smouldering infections in this country which rarely affect humans. An interesting exposition.

ESKEY, C. R. Recent Developments in Our Knowledge of Plague Transmission. Pub. Health Rep. 53, 2:49 (Jan. 14), 1938.

Selling British Health Services—Modestly acknowledging the British health service to be the best in the world, this author points to the fact that less than half the mothers visit antenatal clinics, a third of all infants fail to attend infant welfare centers, and only two-thirds of the school children needing dental treatment get it. This indicates lack of public appreciation of health services, and the outstanding immediate public health objective is to remedy it.

FENTON, J. Knowledge Is the Key to Health. J. Roy. San. Inst. 1, 4:221 (Jan.), 1938.

Credit Where Due—High point of this British paper is the table showing decline in diphtheria deaths in New York contrasted with the continuing high mortality in London. In 50 large British communities, an estimated "immunized" rate of 5 per cent of the total child population is reported.

FORBES, J. G. Progress of Diphtheria Prevention. Brit. M. J., Dec. 18, 1937, p. 1209.

Rheumatic Hearts—If as many cases of polio occurred in any northern city as there are cases of rheumatic heart disease found normally in the hospitals of the same city, what scare headlines we should see! Yet the latter is one of the major public health problems, however apathetic health officials and parents alike may be about it. If the disease were properly reported, both the public and officialdom would be aware of its seriousness, for

it would be exceeded as a cause of death only by tuberculosis, pneumonia, and syphilis, among the communicable diseases.

HEDLEY, O. F. Mortality from Rheumatic Heart Disease in Philadelphia during 1936. *Pub. Health Rep.* 52, 53:1907 (Dec. 31), 1937.

Negro Health in Large Cities—Illnesses which caused incapacity for at least a week were 43 per cent higher among Negroes than similar groups of white residents in 4 large cities. Among both races improved living status decreased the incidence of illness. Low economic status hence may account for much of the higher Negro disability rate.

HOLLAND, D. F., and PERROTT, G. St. J. Health of the Negro. *Milbank Quart.* 16, 1:5 (Jan.), 1938.

Class Differences in Birth Rates—Standardized birth rates were lowest in the \$2,000 to \$3,000 family income class in this survey conducted in 5 large cities and including 16,831 married women of childbearing age. Higher income families had more children, as did those under \$2,000. The relievers were most prolific. Professional groups do better by the country than the business class. Page Mussolini!

KISER, C. V. Variations in Birth Rates According to Occupational Status, Family Income, and Educational Attainment. *Milbank Quart.* 16, 1:39 (Jan.), 1938.

What We Know about Polio—This disconcerting review of the many vacant spots in our knowledge of the prevention of poliomyelitis ends with a warning applicable to other public health situations. In effect, the author says that the public should realize how little science knows of the essential facts of poliomyelitis, and should be spared the premature publication of half truths, or no truths.

LANDON, J. F. Poliomyelitis. *New York State J. Med.* 38, 1:1 (Jan. 1), 1938.

From Jenner to Social Security—An engaging presentation of the development of public health through the protozoan and prevertebrate epochs, the eras of fumigation and environmental sanitation, then the ages of immunization and personal hygiene up to the "homo sapiens" stage.

MILLER, K. E. The Evolution of Public Health. *Health Officer.* 2, 8:353 (Dec.), 1937.

Public Schools and Health—What is wrong with New York City schools from the standpoint of the health of the school child is likely to be more or less true of other city systems. As the suggested improvements probably apply elsewhere, the paper might well be read by all who have to do with school child health.

ROSENSON, W. Neglected Health Factors in Public Schools. *New York State J. Med.* 3, 1:7 (Jan. 1), 1938.

Raw Pork Eaters Are Many—Evidence is presented which indicates an incidence of trichinosis among United States adults of about 1 in 5.

SCHEIFLEY, C. H. The Prevalence of Trichinosis. *Am. J. Hyg.* 27, 1:142 (Jan.), 1938.

Will Influenza Immunization Come?—Evidence is presented of the immunizing properties of influenza vaccines prepared from chick embryo virus cultures. Although protection is afforded by intramuscular injections, it is not known how long the immunity persists.

STOKES, J. J., Jr., et al. Vaccination Against Epidemic Influenza with Active Virus of Human Influenza. *Am. J. M. Sci.* 104, 6:757 (Dec.), 1937.

Health Education in School and Community—Discussed here and in a succeeding issue are the qualifications and training of elementary and secondary school teachers in matters of health.

the nature of training for school health supervision, and the administration of general health education programs.

TURNER, C. E., and RILEY, P. L. *The Training of the Health Educator.* J. Health & Phys. Ed. 9, 1:13 (Jan.), 1938.

About Abortions—In this typical cross-section of the general population,

15 per cent of all pregnancies were found to terminate in abortion; the rate in rural areas was less, but not greatly different from the urban; about 5 per cent are induced abortions, 10 per cent spontaneous.

WIEHL, D. G. *A Summary of Data on Reported Incidence of Abortion.* Milbank Quart. 16, 1:80 (Jan.), 1938.

ASSOCIATION NEWS

OFFICERS AND EXECUTIVE COMMITTEE

KANSAS CITY ANNUAL MEETING

DR. Edwin Henry Schorer, Chairman of the Local Committee on Arrangements for the Sixty-seventh Annual Meeting of the Association, to be held in Kansas City, Mo., October 25-28, announces the following appointments of officers and chairmen of sub-committees working for the success of the convention:

Honorable Bryce B. Smith.....	Honorary Chairman
Mayor of Kansas City, Mo.	
Honorable Don. C. McCombs.....	Honorary Chairman
Mayor of Kansas City, Kans.	
Edwin Henry Schorer, M.D.....	Local Chairman
Director of Health, Kansas City, Mo.	
Ralph Duncan, M.D.....	Vice-Chairman
Commissioner of Laboratories, Health Department	
Otto Murphy.....	Vice-Chairman
Commissioner of Inspection & Sanitation	
Albert Jewell.....	Secretary
Health Conservation Association	
William F. Lunsford, M.D.....	Treasurer
Director of Health, Kansas City, Kans.	
Merl P. Moon, Ph.D.....	
President-Elect, Missouri Public Health Association	

Chairmen

Edward H. Skinner, M.D.....	Finance Committee
Jackson County Medical Society	
Ira H. Lockwood, M.D.....	Reception Committee
President, Jackson County Medical Society	
Morris Ginsberg, M.D.....	Publicity Committee
Health Conservation Association	
Carl Ferris, M.D.....	Radio Committee
Jackson County Medical Society	
Max Goldman, M.D.....	Meeting Rooms Committee
Jackson County Medical Society	
H. E. Boning, Jr.....	Registration Committee
Manager, Convention Bureau	
E. L. Filby.....	Scientific Trips Committee
Associate Engineer, Black & Veatch	
Frank Houston.....	Entertainment Committee
Account Executive, Potts Advertising Company	
Mrs. Samuel Sawyer.....	Ladies Entertainment Committee
President, Visiting Nurses Association	
John Williams, Jr., M.D.....	Membership and Attendance Committee
Missouri State Board of Health	
E. K. Musson, M.D.....	Membership and Attendance Committee
Kansas State Board of Health	
Edward A. Plowman.....	Transportation Committee
Supt., Motor Section, Health Department	
Ralph E. Duncan, M.D.....	Housing Committee
Commissioner of Laboratories, Health Department	
Otto Murphy.....	Scientific Exhibits Committee
Commissioner of Inspection and Sanitation, Health Department	

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- George M. Brother, M.D., 204 S. High St., Rising Sun, Ind., Director, Fourth District Health Dept.
- William W. Fuller, M.D., Health Department, Christiansburg, Va., Montgomery County Health Officer
- Elsworth L. Gardner, M.D., Courthouse, Eugene, Ore., City and County Health Officer
- Abraham Gelperin, M.D., 306 Northern Ave., Cincinnati, O., District Physician, Dept. of Health
- Edgar M. Griffith, M.D., Harrisonville, Mo., Director, Cass County Public Health Unit
- F. Sydney Hansen, M.D., City Hall, Pendleton, Ore., County Health Officer
- Joseph L. Hundley, M.D., Wytheville, Va., Wythe County Health Officer
- James Murphy, M.D., 101 Broad St., Middletown, Conn., President, City Health Board
- Samuel B. Osgood, M.D., County Court House, Grants Pass, Ore., Josephine County Health Officer
- J. A. Outland, M.D., Murray, Ky., Calloway County Health Officer
- Vincenzo Pascale, M.D., 38 W. 10 St., New York, N. Y., Medical Inspector and Chief, Bureau of Social Hygiene, Staten Island Case Finding Project, New York City Dept. of Health
- C. L. Putnam, M.D., State Dept. of Health, Des Moines, Ia., Field Representative and Medical Director, District No. 111
- Frederick M. Rauch, M.D., Mohegan Lake, N. Y., Health Officer, Putnam Valley
- William C. Treder, M.D., 138 Mohawk Ave., Scotia, N. Y., Commissioner of Health, Schenectady
- James P. Ward, M.D., Charleston, Miss., Director, Tallahatchie County Health Dept.
- Jabez H. Williams, M.D., Clinton, N. C., Sampson County Health Officer

Laboratory Section

- Frieda Canvel, 10434 Hebron Lane, West Los Angeles, Calif., Bacteriologist, Grade 1, Los Angeles County Health Dept.
- Francis E. Council, M.D., 615 N. Wolfe St., Baltimore, Md., on leave (Captain, Medical Corps, U. S. Army)
- Marjory W. Ellison, 2215 Belmont Blvd., Nashville, Tenn., Technician, Diagnostic Section, State Laboratory

- John P. Greze, Jr., Zonite Products Corp., New Brunswick, N. J., Bacteriologist
- Rowland A. Grote, 807 E. 30 St., Austin, Tex., Pharmacist, Bureau of Laboratories, State Dept. of Health
- Charles A. Hunter, Ph.D., Washburn College, Topeka, Kans., Director, Public Health Laboratories, State Board of Health
- Edward G. Hoffman, Nez Perce County Health Unit, Lewiston, Idaho, Laboratory Technician, North Central Health District
- Blanche Kosecoff, Dept. of Health Laboratories, Ft. of E. 16 St., New York, N. Y., Laboratory Assistant
- Clara S. Lehmberg, State Board of Health, Phoenix, Ariz., X-ray Technician, Mobile Unit
- Samuel L. Leiboff, 1315 Clinton Ave., New York, N. Y., Director, New York Pathological and X-ray Laboratory; Biochemist, Lebanon Hospital
- Howard E. Lind, C.P.H., St. Louis County Health Dept., Clayton, Mo., Director, Bacteriology Laboratory
- Nicholas A. Milone, State Dept. of Health, Albany, N. Y., Junior Sanitarian, Bureau of Milk Sanitation
- Theodore Mitschke, 200 Percival Ave., Kensington, Conn., Laboratorian in Charge, U. S. Veterans' Administration Facility
- Frank P. Pauls, 2521 Durant Ave., Berkeley, Calif., Malaria Microscopist, State Dept. of Public Health
- Isabella B. Romans, 39 W. 38 St., New York, N. Y., Research Bacteriologist, Pease Laboratories
- Virginia Wilson, 507 E. Capitol, Jefferson City, Mo., Laboratory Technician, State Board of Health

Vital Statistics Section

- Anne L. Kell, St. John's Rectory, Glyndon, Md., Statistical Clerk, State Dept. of Health

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITION AVAILABLE

LOS ANGELES COUNTY CIVIL SERVICE COMMISSION

Assistant Health Officer, Health Department. Open to residents of the United States. Men only. M.D. and possess or able to secure certificate to practise in California; possess certificate or degree in public health from recognized school of public health in the United States; 2 years' recent experience in public health work in administrative capacity. Five years' additional experience may be substituted for public health certificate or degree lacking. Vacancies: One. Age: At least 30 years at date of examination. Salary starts at \$450 per month. (Examination given in Los Angeles only.) Applications must be filed by April 15, 1938.

POSITIONS WANTED

HEALTH OFFICERS

Physician, M.D., University of Maryland; C.P.H., Johns Hopkins; broad experience in county public health administration, will consider opening of better class. A346

Physician, M.D., Western Reserve; short course for health officers, Johns Hopkins; with county and state experience, wishes administrative or epidemiological position; north or west preferred. A349

Physician, M.D., Northwestern University; Dr.P.H., Yale; will consider appointment in general administration, infant welfare or epidemiology. A300

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins and 14 years public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Experienced Health Officer, who has completed Vanderbilt short course, 1936, will consider appointment. West preferred. A320

Physician, M.D., Johns Hopkins; Public Health course at Michigan; experienced in school and city health work, will consider an administrative post in eastern United States. A354

Physician; age 33, M.D., University of Wisconsin; M.P.H., Harvard; specializing in industrial hygiene, will consider general administration. A342

Trained administrator, A.B., M.D., with background of laboratory and research; formerly Assistant Health Commissioner large city. Familiar with all lines. Available short notice. A295

CHILD HYGIENE

Experienced physician, M.D. and Ph.D., University of Minnesota; specially qualified in maternal and child hygiene, directing state and local programs; will consider position of better sort. A238

Woman physician, M.D., Creighton Medical School, with extensive experience in maternal, infant and child hygiene, and special interest in crippled children's service, desires position in field work. C301

Woman physician, M.D., Rush Medical; wishes administrative or clinical position in maternal and child health. C347

Woman physician, M.D., Yale; Dr.P.H., Yale; experienced in pediatrics and administration of state bureau, will consider attractive opening. C348

SANITARY ENGINEERING

Sanitary Engineer, courses at Rutgers University, with 17 years' experience in design, research and construction of water and sewage plants, as well as aerial pollution surveys, desires position, preferably research. E321

Graduate Sanitary Engineer with service under U.S.P.H.S. and State Departments of Health, especially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

MISCELLANEOUS

Young woman, M.S.P.H., University of Michigan, experienced in laboratory research and health education, is available for research or investigative work. M303

Young man, at present college teacher of hygiene and physical education and experienced in university medical service, desires position as executive in public or private health organization. M357

NEWS FROM THE FIELD

MODEL ORDINANCES

THE A.P.H.A. Information Service frequently receives requests from health officers and others asking for information about model ordinances on a great variety of subjects. In the absence of any comprehensive publication on model ordinances, the Information Service is thrown back on those cities and other municipalities which have advised the Association of regulations proved to be satisfactory.

The Information Service would welcome receipt of copies from any health officer who has ordinances of merit which he would recommend for the consideration of other areas. Address the Executive Secretary, American Public Health Association, 50 West 50th Street, New York, N. Y.

UNIVERSITY OF MINNESOTA IN-SERVICE FELLOWSHIPS IN PUBLIC ADMINISTRATION

THE University of Minnesota offers a limited number of in-service fellowships in public administration for the academic year 1938-1939. These are available to promising young men and women now in the service of government in order that they may better equip themselves to fill positions involving administrative leadership and responsibility. It is also the aim to encourage governmental bodies to give recognition to these persons in making promotions to administrative posts.

Applicants must be citizens of the United States, not over 35 years of age, graduates of recognized universities and colleges, and must qualify for admission to the graduate school at the University of Minnesota. They must have had not less than three years of experience in public service, preferably

in a position involving some administrative responsibility. Each applicant for an in-service fellowship must be endorsed by his governmental employer. Credit earned in residence at the University during the training period may be applied toward advanced degrees. Applications are to be submitted not later than April 1, 1938, and appointments will be announced May 15 or as soon thereafter as possible. Requests for application blanks and for further information should be addressed to the Secretary of the Committee on Training for Public Health Administration, 13 University Library, University of Minnesota, Minneapolis, Minn.

TUBERCULOSIS RULING

GEORGE C. Ruhland, M.D., of Washington, D. C., Health Officer of the District of Columbia, has reported a test case of the right of the Health Department of the District of Columbia to prevent a man from spreading tuberculosis to his children and other persons in the community. The Police Court ruled that the tuberculous patient could take his choice of paying a fine or receiving treatment in a sanatorium. A summary of the case follows: The patient was 73 years old, a night watchman. He had a wife 30 years old and 4 children ranging from 8 months to 9 years of age. A private physician reported the man to have tuberculosis in July, 1936. He failed to keep appointments at the clinic, and refused admittance to visiting nurses. He refused to have his children examined. On January 13, 1938, the Police Court ruled that Solomon Bell violated the laws of the District of Columbia relating to the prevention of tuberculosis.

DR. COGSWELL HONORED

DR. W. F. Cogswell, Montana's State Health Officer for the past 25 years, was honored at a Silver Anniversary banquet given by members and employees of the State Board of Health on January 17, in Helena. More than 80 persons were present, and 50 messages of greeting and congratulation were received by Dr. Cogswell.

Dr. Cogswell was first named Secretary of the Montana State Board of Health in 1912. In that year he was also Secretary of the Montana Public Health Association. When the State Board of Entomology was created in 1913, he was named chairman, and it was largely through his efforts that, in 1923, the Rocky Mountain Tick Laboratory for the study of spotted fever was established in Hamilton, Mont., and, in 1931, transferred to the U. S. Public Health Service.

In 1920, he was president of the State and Provincial Health Officers of North America, and in 1936, he was president of the Western Branch of the American Public Health Association.

Among the many letters received were those from Dr. Thomas Parran, Surgeon-General, and Dr. A. T. McCormack, President of the A.P.H.A. Another letter was from Joseph Brown, chairman of the Blackfeet Tribal Council, extending greetings to their "Chief Little Bull," Dr. Cogswell's tribal name.

VENEREAL DISEASE COURSE

A ONE-WEEK refresher course in venereal disease control is being offered at Western Reserve University, Cleveland, Ohio, open to any regularly licensed physician in Ohio, without fees.

This is a shortening of the graduate course recently announced as planned to cover 3 or 4 months. The short

course will consist of formal lectures on the several venereal diseases and demonstrations of methods of examination and treatment.

Further information and a copy of the working schedule may be obtained from George W. Binkley, M.D., 2085 Adelbert Road, S.E., Cleveland.

CANADIAN PUBLIC HEALTH ASSOCIATION MEETING

THE next annual meeting of the Canadian Public Health Association will be held in Halifax, N. S., from June 20-22, 1938.

The Lord Nelson Hotel will be the convention headquarters.

TRANSACTIONS OF THE CONGRESS ON HYGIENE

THE State Health Department of Maryland has a limited number of the Transactions of the Fifteenth International Congress on Hygiene and Demography meeting in 1912, which it will be glad to distribute without cost to any physician, public health official, or library, desiring a set. The set consists of 6 volumes dealing with the following subjects.

Volume I, Part I.—Organization and Membership. Part II.—Proceedings of the Joint Sessions and General Index. *Volume II*, Part I.—Hygienic Microbiology and Parasitology. Part II.—Dietetic Hygiene; Hygienic Physiology. *Volume III*, Part I.—Hygiene of Infancy and Childhood; School Hygiene. Part II.—Hygiene of Occupations. *Volume IV*, Part I.—Control of Infectious Diseases. Part II.—State and Municipal Hygiene. *Volume V*, Part I.—Hygiene of Traffic and Transportation. Part II.—Military, Naval, and Tropical Hygiene. *Volume VI*.—Demography.

Applications should be sent to Dr. Robert H. Riley, Director, State of Maryland Department of Health, 2411 North Charles Street, Baltimore, Md. The sets will be sent with express charges collect.

CANADIAN PUBLIC HEALTH ASSOCIATION ADOPTS STANDARD METHODS

ON the recommendation of the Section, the Canadian Public Health Association has adopted officially the Standard Methods for the Examination of Water and Sewage, as prepared by the American Public Health Association and the American Water Works Association, subject to the incorporation of such alternative methods as may be deemed necessary.—The Sixth Annual Christmas Meeting of the Laboratory Section of the Canadian Public Health Association, 1938. *Canad. Pub. Health J.*, Jan., 1938.

REGIONAL LABORATORIES

UNDER the provisions of the Bankhead-Jones Act, three new regional laboratories for the investigation of regional problems in agriculture were approved during the fiscal year ended June 30, 1937. The new regional laboratories include one for the study of animal parasites in the southeast, one for the development of swine breeding in the north central states, and one for sheep improvement in the range states.

The laboratory for the study of diseases and parasites of domestic animals is being established at the Alabama Polytechnic Institute, at Auburn. The experiment stations of 13 southeastern states are coöperating with the U. S. Department of Agriculture in the development of the program for regional studies, which will be under way in all the states with headquarters and coordinating direction at Auburn. The states are: Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, Tennessee, Kentucky, and Oklahoma.

Regional research has been made possible by appropriations under the

Bankhead-Jones Act, which, unlike previous legislation for the support of experiment stations, require state appropriations to offset the federal contributions. Each state complied with this requirement and, on the average, state appropriations were several times the amount required under this provision.—*J. Am. Vet. Med. Assoc.*, Feb., 1938.

NORTH CAROLINA SYPHILIS CAMPAIGN

ACCORDING to the *Journal of the American Medical Association*, the Zachary Smith Reynolds Foundation is devoting the entire income from its funds, amounting to \$7,000,000, to finance a campaign against syphilis in North Carolina. The income is stated to be more than \$100,000 a year, and this amount has already been presented to the State Board of Health for the first year's work.

The State is now operating 67 clinics for venereal disease and the new fund will be used to expand about 12 of these in the more populous counties. For rural districts a clinic on wheels, consisting of a motor truck fitted as a physician's office and accompanied by a doctor and a nurse, will be developed as one of the first projects.

The plans are under the direction of Carl V. Reynolds, M.D.,† of Raleigh, the State Health Officer.

MARYLAND SUMMER CAMPS

OWNERS and operators of summer camps in Maryland—tourist, recreational, and labor—have been notified by R. H. Riley, M.D.,* Director of the State Department of Health, that all camps in Maryland must be inspected and duly licensed before they may be opened for visitors. Permits do not hold over from year to year. Whether the camps are old or new, permits must be secured for the coming season. No camp may be operated without one.

* Fellow A.P.H.A.

† Member A.P.H.A.

The regulations apply to every camp or picnic ground that is used for a period of 6 days or longer.

PARENTS' MAGAZINE AWARDS

SURGEON General Thomas Par-ran's crusade against venereal disease and Irene Wicker's 8 years of broadcasting as *The Singing Lady* receive this year's awards for outstanding service to children given by *The Parents' Magazine*. The announcement is made in the March issue of the magazine.

In previous years only one award was made. Other winners were: Walt Disney, 1934; Grace Abbott, 1935; Walter Damrosch, 1936; Dr. Allan Roy Dafoe, 1937.

NURSES' BIENNIAL CONVENTION

THE Biennial Convention of the 3 national nursing organizations—the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing—will be held in Kansas City, Mo., April 24–29. The Hotel President will be the convention headquarters.

The central theme of the Biennial will be "The Individual Nurse's Responsibility for Professional Progress."

NEW YORK HEALTH DEPARTMENT NURSING IN 1937

MEMBERS of the New York City Health Department Nursing staff made over 600,000 visits in 1937, according to the February issue of *Our Nurses*, issued February 5.

Of the total 600,000 visits, about 100,000 were made to infants and pre-school children, 280,000 to homes of school children, 110,000 to homes of tuberculous patients, and 6,000 to cases of acute contagion.

PERSONALS

Central States

DR. LOUIS P. H. BAHRENBURG, Director of the U. S. Marine Hospital of the U. S. Public Health Service, at Cleveland, Ohio, has retired. He is succeeded by **DR. FRANK M. FAGET**, Senior Surgeon in the Service, who has been at the Marine Hospital in Louisville, Ky.

DANIEL C. BARRETT, M.D., C.P.H.,† has become Director of the Washington County Health Unit, Iowa. Dr. Barrett was formerly District Physician for the Cincinnati, Ohio, Health Department.

FRANCIS B. CARROLL, M.D., C.P.H.,† of Paw Paw, Mich., has resigned as Director of the Van Buren County Health Department to join the Division of Communicable Diseases of the Massachusetts Department of Health, Boston, Mass.

DR. FRED A. DENNIS, of Crawfordsville, Ind., has been appointed Health Officer of Montgomery County, succeeding **DR. JAMES S. NOBLITT**, of Waveland.

DR. JOHN C. GLACKMAN, of Rockport, Ind., has been appointed Health Officer of Spencer County.

ALFRED G. LONG, M.D., C.P.H.,* of Kokomo, Ind., has been appointed Health Officer of the City of Miami Beach, Fla.

MRS. BLANCHE R. MILLER, of Cincinnati, Ohio, has been appointed Supervisor of Health Education of Cincinnati, a newly created position. Mrs. Miller will develop a program of health education in the schools and the community in the campaign against tuberculosis.

JOSEPH G. MOLNER, M.D., C.P.H.,† and **FRANKLIN H. TOP, M.D., C.P.H.,†** both of Detroit, will divide the responsibilities of the position

* Fellow A.P.H.A.

† Member A.P.H.A.

of Deputy Health Commissioner of Detroit, Mich., succeeding DON W. GUDAKUNST, M.D.,* who recently resigned to become State Health Commissioner.

DR. IRA E. PERRY, of North Manchester, Ind., has been appointed Health Officer of Wabash County, succeeding DR. ARTHUR J. STEFFEN, of Wabash.

DR. CARL M. PORTER, of Jasonville, Ind., has been appointed Health Officer of Greene County, Ind.

DR. CHARLES L. WISE, of Camden, Ind., has been appointed Health Officer of Carroll County, succeeding DR. ALBERT C. CLAUSER, of Delphi.

Eastern States

I. HOPE ALEXANDER, M.D.,† has been reappointed Director of Health of Pittsburgh, Pa.

FRANK A. CALDERONE, M.D., C.P.H.,† of Jericho Turnpike, Westbury, N. Y., is leaving the service of the State of New York and entering that of the City as District Health Officer of the Lower East Side Health Office, at 73 Cannon Street, New York, N. Y.

DR. ARTHUR J. COUTURE, of Moosup, Conn., has been appointed Health Officer of Sterling, for 4 years.

H. JACKSON DAVIS, M.D., DR.P.H.,* Assistant Director of Local Health Administration, New York State Department of Health, Albany N. Y., has become Chief Medical Officer on the staff of the State Department of Social Welfare. In addition to regular and special assignments in the department, Dr. Davis was Director of Medical Care for TERA until June 30, 1937; during the preceding 5 years he was responsible for the distribution of more than \$10,000,000 in medical relief in the state. He has also been responsible

for administering details of 44 TERA "work relief projects" employing needy physicians, dentists, nurses, and other public health personnel. In addition to his assignment as TERA Director of Medical Care, Dr. Davis served as WPA Consultant on Medical Care for upstate New York soon after it was organized in 1935.

ROBERT D. JOHNSON, M.D., has been appointed Director of the Bureau of Tuberculosis in the Department of Health of Syracuse, N. Y., succeeding HENRY BURTON DOUST, M.D.

DR. CHARLES A. KRAUS, Professor of Chemistry and director of chemical research at Brown University, Providence, R. I., has been elected President of the American Chemical Society for 1939. DEAN FRANK C. WHITMORE, of Pennsylvania State College, State College, Pa., is President for 1938.

DR. JAMES H. LADE, who recently completed a fellowship in syphilis at Johns Hopkins Hospital, has been appointed Medical Consultant in the Division of Syphilis Control, New York State Department of Health.

DR. GEORGE S. LAMBERT has been appointed Health Officer in the Borough of Danielson, and Acting Health Officer of Killingly, Conn.

GOODHUE LIVINGSTON, Jr., of New York, N. Y., has been sworn in as Secretary of the New York City Health Department.

GREGORY D. MAHAR, M.D.,† Commissioner of Health of Syracuse, N. Y., has returned at his own request to his former position as Senior Epidemiologist in the Syracuse Health Department.

ELEANOR W. MUMFORD, R.N., formerly Assistant Director of the National Organization for Public Health Nursing, has been appointed Associate for Nursing Activities by

* Fellow A.P.H.A.

† Member A.P.H.A.

the National Society for the Prevention of Blindness, succeeding FRANCIA BAIRD CROCKER, R.N.

MAURICE G. POSTLEY,† formerly Secretary of the New York City Health Department, has been appointed Secretary of the New York City Board of Education.

Southern States

DR. JAMES H. BUNN, JR., formerly of Henderson, has been appointed head of a new health unit in Johnston County, with headquarters in Smithfield, N. C.

DR. CHARLES F. ENGELKING has been reappointed Health Commissioner of Dalton and Whitfield County, Ga.

W. S. LEATHERS, M.D.,* Dean of the School of Medicine, Vanderbilt University, Nashville, Tenn., received the Doctorate of Humane Letters from Tulane University, New Orleans, La., on the occasion of the installation of DR. RUFUS C. HARRIS as President. The same degree was awarded REV. ALPHONSE M. SCHWITALLA, PH.D., S.J.,† Dean of the School of Medicine, St. Louis University, St. Louis, Mo.

DR. FRANCIS F. SCHWENTKER resigned as Director of Medical Research in the Baltimore City Health Department January 1, to study scarlet fever in Rumania under the auspices of the Rockefeller Foundation.

DR. LOREN WALLIN, formerly of Sparta, Ga., has been appointed Health Officer of Anson County, N. C., a new health unit.

Western States

DR. PAUL R. ENSIGN, formerly of Butte, Mont., has been appointed Pediatrician to a child health demonstration in Hancock-Glascock Counties, Ga.

SAMUEL WEISSROSS, M.D.,† of Boise, Assistant Director of Public Health, of the Idaho State Department of Public Welfare, has taken charge of

industrial hygiene activities and of medical statistics.

Canada

ADELARD GROULX, M.D., C.P.H., of Montreal, Quebec, has been appointed Director of the Department of Health of the City of Montreal, succeeding SERAPHIN BOUCHER, M.D.,* retired.

DEATHS

GEORGE HENRY FALKINER NUTTALL, M.D., F.R.S., died suddenly in England, at the age of 75. He was born in San Francisco. He received his medical training in the University of California, Johns Hopkins, and Göttingen. He was assistant to Dr. William H. Welch at Johns Hopkins University in 1890, and later became Associate in Hygiene. He taught bacteriology and preventive medicine in Cambridge, and in 1895 became Reader in Hygiene. He was appointed Quick Professor of Biology, and was elected a professorial Fellow of Magdalene College. His researches are incorporated in more than 200 unpublished papers, and cover bacteriology, serology, hygiene, tropical medicine, and parasitology. His most important discovery was the bactericidal property of the blood serum and other body fluids, which is credited as the pioneer work in immunology.

ETHEL M. HANSON, for 20 years Director of the Health and Parent Education Association of Cleveland, Ohio, died recently.

W. F. ROBERTS,† Minister of Health and Labor for New Brunswick and the first Minister of Health in the British Empire, died at Saint John, N. B., February 10, at the age of 68.

JOHN N. RYAN, M.D.,† Health Officer of Passaic, N. J., for 26 years, died February 10.

Certain Criteria in the Qualifications and Preparation of Health Officers*

HENRY E. MELENEY, M.D.

*Department of Preventive Medicine and Public Health, Vanderbilt
University School of Medicine, Nashville, Tenn.*

THE United States is faced with certain special problems in the selection of qualified health officers. The country contains regions so different in geographical conditions, resources, interests, and types and concentration of population, that its public health problems are diversified. The autonomy of our state and local governments in matters of health makes it difficult to obtain the adoption of uniform standards for the selection of health officers. The traditional association of public office with political preferment rather than with qualifications for efficient service has hindered progress and discouraged many persons of high caliber from entering governmental employment.

There are certain advantages in the autonomy of state and local govern-

ments which may counteract the benefits of the uniformity created by centralized federal control. Local responsibility, when it is assumed by skillful, conscientious leadership, encourages initiative and tends to develop higher standards than can usually be attained under remote governmental control; but where the people of a community are uninformed as to the qualifications necessary for efficient service, or where appointments of professional personnel remain on a political basis, autonomy is a liability rather than an asset.

Much progress has been made in the past few years in stabilizing the profession of public health and in crystallizing opinion concerning the qualifications of those who are to enter the profession. Educational facilities have been extended and improved and opportunities have been provided for an increasing number of individuals to take advantage of these facilities.

* Read at a Special Session of the Committee on Professional Education of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

EDUCATIONAL STATUS

In order to obtain some estimate of the present educational status of the health officers of the country I have made a summary of the professional degrees and certificates held by state and insular health officers, by whole-time county and district health officers, and by the whole-time and part-time health officers of cities of 10,000 or more population, as reported for 1936 by the United States Public Health Service.^{1, 2, 3} While the mere possession or lack of a professional degree cannot be taken as a measure of the efficiency of a health officer, it does give some indication of his accredited educational equipment.

The analysis of the degrees and certificates held by state and insular health officers is shown in Table I. All of these health officers hold a medical degree and 12 of the 55, or 22 per cent, hold an additional public health degree. It is obvious from this analysis that the states recognize the importance of a medical education as a qualification for the directors of their central health organizations. Many of the state health officers who do not hold an additional public health degree have had long experience in public health and are among our ablest leaders in this field. These men have so firmly established themselves by their accomplishments that political influences usually cannot remove them from office. Many states require the appointment of highly qualified state health officers, and in some cases nominations for the position are made by nonpartisan boards, thus insuring the selection of qualified individuals. It is to be hoped that in the near future legislation and custom will remove the appointment of all state health officers from political control. These positions are the keystones in the American system of local health administration, and the future success of this system depends largely

upon the stabilization of state health officials on a high plane of efficiency.

TABLE I

Number and Percentage of State and Insular Health Officers Holding Various Degrees, 1936

<i>Degree</i>	<i>Number</i>	<i>Per cent</i>
M.D.	43	78.2
M.D. + C.P.H.	6	10.9
M.D. + D.P.H.	1	1.8
M.D. + Dr.P.H.	5	9.1
Total	55	100.0

The analysis of the degrees and certificates held by whole-time county and district health officers (Table II) shows that, of the 574 officers listed, 87.5 per cent hold a medical degree alone, and 12 per cent hold a public health degree in addition to a medical degree. Only 3 full-time county health officers lack a medical degree, 1 of whom holds a bachelor of science degree in public health, 1 a master of science degree alone, and 1 no degree. It is probable that a majority of the full-time county health officers holding medical degrees alone have received some kind of postgraduate instruction in public health, and under the present arrangements sponsored by the U. S. Public Health Service most of the others who can benefit by such instruction will undoubtedly receive it in the near future.

TABLE II

Number and Percentage of Whole-time County Health Officers Holding Various Degrees, 1936

<i>Degree</i>	<i>Number</i>	<i>Per cent</i>
M.D.	502	87.5
M.D. + Public Health	69	12.0
B.S. or M.S.	2	0.3
No degree	1	0.2
Total	574	100.0

The analysis of degrees and certificates held by city health officers is

shown in Table III. It is divided into cities having a population of 50,000 or more, and those having a population of 10,000 to 50,000. Among 191 cities of 50,000 or more population the analysis shows that 69 per cent have whole-time health officers, 31 per cent have part-time. Among the 131 whole-time health officers 74 per cent hold a medical degree without a graduate degree in public health, 13 per cent a medical and a public health degree, 2 per cent a public health or sanitary engineering degree without a medical degree, 2 per cent a veterinary or pharmacist degree, and 8 per cent no degree. Among the 60 part-time health officers, all hold medical degrees and 1 an additional public health degree.

nurses or public health nurses; and 38 per cent hold no degree. Among the 433 part-time health officers, 90 per cent hold a medical degree, 4 of which are supplemented by public health degrees, 2 per cent hold other degrees, and 8 per cent hold no degree.

A further statement is necessary concerning the status of city health officers who hold no degree. Among the cities of 50,000 or more population there are 11 in which the person designated as health officer holds no degree. Eight of these have the official title of health officer or its equivalent. The other 3 have the official title of clerk, agent, or executive officer of the board of health. Among the smaller cities there are 146 in which the person

TABLE III

Percentage of City Health Officers Holding Various Degrees, 1936

	<i>Cities of 50,000 and Over Population</i>		<i>Cities of 10,000 to 50,000 Population</i>	
	<i>Whole-time</i>	<i>Part-time</i>	<i>Whole-time</i>	<i>Part-time</i>
Number of health officers	131	60	290	433
Per cent whole-time or part-time	68.6	31.4	40.1	59.9
<i>Degree</i>				
M.D.	74.0	98.4	44.1	89.0
M.D. + Public Health	13.0	1.6	11.0	0.9
Public Health or Engineering	2.3	0.0	1.7	0.2
Other Degrees	2.3	0.0	3.1	1.4
Regist. Nurse or Public Health Nurse	0.0	0.0	2.1	0.2
No Degree	8.4	0.0	37.9	8.3
Total	100.0	100.0	99.9	100.0

The analysis for 723 cities having a population of 10,000 to 50,000 shows that only 40 per cent of these cities have whole-time health officers while 60 per cent have part-time. Among the 290 whole-time health officers 44 per cent hold a medical degree alone; 11 per cent a medical degree and a public health degree; 2 per cent only a degree in public health or sanitary engineering; 3 per cent a veterinary, optometrist, pharmacist, or other graduate degree; 2 per cent are registered

designated as health officer holds no degree. Of these, 75 per cent have the official title of health officer or its equivalent, the others have various titles, such as clerk, agent, sanitary inspector, or chief of police. Thus the large majority of these officials are considered health officers, and although a few of them may hold an academic degree which is not mentioned in the report, it is probable that most of them do not possess the professional qualifications necessary for an efficient

health officer. Seventy-seven per cent of the health officers possessing no degree are in 3 northeastern states. This indicates that there must be special circumstances in these states responsible for the selection or designation of non-professional persons as health officers. In one a bill requiring the appointment of highly qualified city health officers has been defeated in the legislature every year for a number of years; in 1 there is a licensing law for health officers which does not require adequate academic qualifications; and in 1 the state health department is handicapped by political influences. It would seem advantageous for every state to possess a statute requiring professional qualifications of city health officers as well as of all other public health personnel within its jurisdiction.

In communities having poorly qualified official public health personnel, it is probable that much of the public health program is carried on in an uncoordinated manner by voluntary organizations, sometimes in the face of opposition from the entrenched and inadequate official agency. It is reasonable to ask whether such communities are not deluded by a false sense of security with regard to the health of their people, whether they really know the amount of preventable disease in their midst, and whether they are not wasting both tax money and voluntary contributions by failure to unify the work under full-time qualified personnel.

Most cities of 50,000 or more should be able to meet the financial requirements for employing a well qualified full-time health officer, but in smaller cities this is often impossible. The difficulty, however, can be solved by combining the full-time health service of such cities with that of neighboring towns or the surrounding rural area. This arrangement, which has already proved successful in a number of

localities throughout the country, offers the additional advantages of unifying effort in communities having common interests and of creating a spirit of coöperation where unpleasant rivalry might otherwise exist.

BASIC QUALIFICATIONS

The necessary qualifications of an efficient health officer may be divided into personal, preliminary educational, and professional. The most important personal qualifications are integrity, leadership, and administrative ability. These are assets which should be possessed by any person who is to occupy an influential administrative position in a community.

The preliminary educational qualifications of an efficient health officer are those required of anyone who is to meet all classes of people in the community on an equal footing. The broader this educational background is the better prepared the health officer will be to deal wisely with the complex problems involved in the health of the community. Many human ills lie largely outside the realm of technical procedures and require a broad outlook for their correction. The most recent trend in college education is toward the preparation of students for intelligent citizenship, with a background of history, language, the sciences and the arts, and such a background the health officer should have.

Professional qualifications must, of course, be developed on the foundation of general education, continuing certain subjects which were started in the preliminary educational period and adding the more technical subjects which enter into public health practice. This is the function of schools of medicine and public health.

The two most important fields of study in the educational equipment of the health officer are the biological sciences and social sciences. In the

social sciences he should have adequate preparation in psychology, sociology, economics, and government. Elementary instruction in these subjects should be received in the preliminary educational period, and this should be followed up in the period of professional study by courses on the special phases of these subjects which are related to public health.

In psychology the health officer must deal with the normal and abnormal reactions of individuals, organizations, and communities, and he must be able to influence them into action. In sociology he must understand heredity, racial problems, population trends, urban and rural relationships, and crime. In economics he must be able to get the most out of his limited budget and he must understand the financial problems of the industrial or agricultural groups of his community. In government he must understand the philosophy and machinery of national, state, and local government, must protect his program against political manipulation, and must know his legal rights and limitations.

An adequate background in the biological sciences is, however, the essential element in the educational equipment of the health officer. Certainly no one can approach health problems intelligently without an appreciation of human and environmental biology. Elementary instruction can be obtained in the introductory courses in general biology offered in colleges, which include the fundamentals of botany, zoology, evolution, and heredity. This is logically followed by a course in vertebrate anatomy and embryology such as is required of premedical students. These courses are merely a foundation for the study of human biology and should be followed by courses in the basic medical sciences, namely, human anatomy, biochemistry, physiology, pathology, and bacteriology. These

provide a familiarity with the normal and pathological conditions of the human body, and its reactions to environment and invading microorganisms. Such a biological background has been considered by some to be adequate for a health officer, but if he is to be fully equipped for his work he should also be familiar with the fundamentals of clinical medicine, surgery, pediatrics, obstetrics, and psychiatry, all of which are intimately related to public health.

THE MEDICAL DEGREE

A word may be said concerning the requirement that all health officers should possess a medical degree. Obviously, the mere possession of such a degree without administrative ability, personal qualifications, and a knowledge of the principles of public health does not qualify a person to be a health officer. Too often in the past poorly qualified physicians have been appointed because of personal or political friendships, and it is these appointments which have occasioned criticism. Such physicians, however, have failed in spite of a medical degree rather than because of it. Graduates in medicine certainly possess administrative and personal qualifications comparable to those of other educational groups, and because the medical degree places the health officer in a position of equality and professional intimacy with the physicians of his community, there is every reason for taking advantage of the increasing supply of young men possessing a modern medical background. This advantage is all the greater in view of the fact that preventive medicine and public health are becoming major subjects in the undergraduate medical curriculum.

This reference to the advantages of utilizing medical graduates as health officers should not be interpreted as excluding from consideration well quali-

fied persons who do not possess a medical degree. By this I mean persons who have completed the basic medical sciences followed by 2 years of academic instruction in public health and a period of field experience. One so equipped may become an able administrator in public health, but it should be recognized that his field of activity may be limited to communities in which he can employ graduates in medicine to supervise the medical activities of his department. In view of such possible limitations it is advisable to recommend that all persons looking forward to a career as a public health officer should obtain a medical degree prior to postgraduate instruction in public health.

POSTGRADUATE INSTRUCTION IN PUBLIC HEALTH

Whether or not a candidate possesses a medical degree, he must supplement his general background by the technical training furnished by a postgraduate course in public health if he is to become fully qualified. The subjects usually required in schools of public health are biostatistics, epidemiology, public health administration, public health bacteriology, sanitation of water, sewage and foods, communicable diseases and nutrition. In addition, instruction should be given in mental hygiene, health education, governmental organization, and social work. Subsequent to intramural instruction there should be practical field instruction in a well organized health department under adequate supervision.

It would be ideal if all states and local communities could now require a full year of postgraduate study as a qualification for health officers. It should be required by all states at least for the professional personnel of their central organizations. For small cities and rural areas, however, a reasonably efficient full-time public health service

may be developed by the employment of medical graduates who have received shorter postgraduate instruction. Such short courses may take the form of orientation in all the important phases of public health work, or they may cover the work of one term in a course leading to a certificate or master's degree in public health. The orientation type of course is also valuable for physicians who have acted as health officers for a number of years without previous academic instruction in public health, but who are too old to be admitted to courses covering a full academic year. Younger men who take such an orientation course should be given the benefit of a full year of postgraduate instruction at a later time if their record of service warrants it.

NEEDS AND OUTLOOK FOR THE FUTURE

The present educational needs for the professional preparation of health officers in this country include both an improvement and expansion of the facilities for extended postgraduate study and a continuation and strengthening of short courses of instruction. As the immediate demand for full-time health service becomes satisfied, the shorter periods of instruction will be replaced by courses of adequate length, and every effort should be made to hasten this development.

Meanwhile, replacement of non-professional health officers should be encouraged, minimum standards should be raised, and information should be given to communities which will assist them in improving and stabilizing their public health personnel. States can encourage their local communities along these lines by enacting legislation requiring the appointment of qualified personnel, by educating local governing bodies, and by subsidizing full-time local health service.

Legal requirements for the selection of health officers, such as age, residence,

civil service, professional degrees, and practical experience, as well as procedure in making appointments, are matters determined by statute and will always differ to a certain extent in various states and communities. They are pertinent to this discussion only in so far as they set limitations which will affect the selection of persons having the best qualifications.

As long as states and local communities retain a relative degree of autonomy they will set their own standards and select their own health officials. A few will probably retain archaic requirements of residence or even political affiliation, and will thus automatically limit the possibility of securing the best service. Others will develop a career service based upon the best obtainable personnel, and will provide their appointees with opportunities for security, advancement, adequate remuneration, and further education, which will bring rewards to the people in the form of better health.

Standardization will limit progress and should be avoided, but an agreement should be reached as to the basic principle that every community should be provided with an adequate full-time health service, under the direction of a highly qualified health officer who is free from political domination. On such a foundation professional standards can constantly be raised to meet the increasing demands for more efficient service. The United States contains a wealth of material for this movement, which only asks that the door of opportunity be opened and a successful future promised in order to produce results which will assure continuous improvement in our national health.

Rural Health Services

“THE survey of rural health services in the United States for the calendar year 1936 showed that there was a net gain of 331 in the number of counties under full-time health administration over the number reported for the previous year. The total number is now in the neighborhood of 1,000. There are now 6 states in which all counties are served by full-time county or district health units, as compared with 3 so organized at the close of the calendar year 1935. The percentage of the total rural population now enjoying this service is estimated at 41.7 per cent. It has been interest-

ing to note in a number of states a trend toward utilization of the district plan to a greater extent in the organization of local health service. In spite of these highly encouraging facts, however, there are still 10 states which do not have any local health service corresponding to the generally accepted standards implied by this term.”—From “A Brief Review of Progress in the Public Health Program under Title VI of the Social Security Act.” C. E. Waller, Assistant Surgeon General. U. S. Public Health Service—*The Health Officer*, February 1938.

The Physician's Statement of Cause of Death*

A. HARDISTY SELLERS, M.D., D.P.H.

*Department of Health for Ontario, and School of Hygiene,
University of Toronto, Toronto, Ont.*

THE physician's statement of cause of death is an important scientific document. It provides information respecting past medical and public health experience, and signposts to problems affecting the health and longevity of our people now and in the future. Accurate mortality records are of great sanitary importance, and progress in medicine and public health has been substantially furthered by them. In the future, too, further guidance in public health will be expected from these records. It is therefore important that every effort be made to improve the reliability and accuracy of statements on the medical certificate in such a fashion that official data will likewise become more accurate and thus more valuable.

There are 3 aspects of medical certification to which we should give special thought: (1) the education of physicians and medical students in the principles and practice of death certification, (2) the form of the questions relating to cause of death, and (3) the statistical practices to which medical statements are subjected when the data are being tabulated.

EDUCATION OF THE MEDICAL PROFESSION IN DEATH CERTIFICATION

Every physician appreciates in a general way the importance of the collection, tabulation, and analysis of mortality statistics. It is doubtful, however, if many of them realize the importance of care and judgment in making their statements. It was with this in mind that the Commission revising the *International List of Causes of Death* in 1929 expressed the opinion that "it was of the utmost importance that medical practitioners and medical students be given special instructions as to the principles governing death certification." The achievement of accurate statements which reflect physicians' considered opinion, depends first upon physicians understanding clearly the significance of the questions relating to cause of death and the general principles upon which death certification is based. Official records can never be more accurate than the statements of medical practitioners, no matter what conventional treatment of them be employed. Education of the profession, particularly medical students, in the purpose and use of the medical certificate is therefore a first essential. A beginning in this respect has been made in Canada through the introduction of an exercise on medical certification as part of the instruction

* Read before the Vital Statistics Section of the American Public Health Association, at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

in 6 medical schools.¹ Undoubtedly this effort will aid substantially in improving medical certification in Canada in the future.

What does the physician need to know to enable him to complete a satisfactory medical certificate? He must first understand clearly what is meant by "cause of death" for statistical purposes. This is defined as "the disease or injury which initiated the train of events leading to death," and it is this entity of which a clear indication is desired. This definition is designed so that medical records may serve to direct attention to the point at which preventive measures may best be applied. Detailed statements are not desired, a single entry being preferable in all cases where this can be regarded as adequate. The physician's statement of cause of death is not intended to be an abstract of the clinical history and pathological findings. Detailed studies in any case can and should always be made on samples where greater reliability may be attached to such detail, as in hospitals. Death certificates should be expected to contain merely a clear, authoritative, scientific, and logical expression of medical opinion as to the cause of death. An entry of several morbid conditions or states has, of course, no particular disadvantage from the medical or statistical standpoint if they are presented in logical order and without ambiguity.

Given a clear understanding of what is meant by "cause of death" for statistical purposes, it is then necessary that physicians be well acquainted with the significance of the questions relating to cause of death, whatever form they may take, so that they may avoid the many common errors and not obscure their statements by incorrect entries.

"The writing of a satisfactory death record is often a matter of no small

difficulty," but "a considerable service can be rendered to the preventive medicine of the present and of the future by each physician, surgeon, and pathologist who endeavors to produce correct and complete mortality and notification records."² Time can surely be found to impress these things upon every medical student before graduation.

FORM OF THE QUESTIONS RELATING TO CAUSE OF DEATH

The medical certificate "should be so planned as to give the physician the opportunity of clearly expressing his opinion as to the cause of death in each individual case."³ At the same time, the order of statement needs to be such as to separate contributory causes which *are related* to the disease causing death (secondary or complicating conditions), and those which are considered contributory factors in causing death but entirely *independent* of the underlying condition responsible for the fatal outcome. Given such a method of orderly statement and the coöperation of the medical profession, it should be possible to eliminate almost entirely the use of arbitrary rules and also to dispense with a request for duration or date of onset which has little or no scientific accuracy in most cases when recorded anyway.

From the national viewpoint it matters not what form the medical questions take in another country, but in each country individually this question should be regarded as one of special importance. At present there are almost as many editions of the medical certificate as there are countries using the *International List*. This is undoubtedly an important factor in limiting international comparability of records apart entirely from variation in rules of choice for joint cause selection. Indeed, even were the latter uniform it would be impossible to expect much

in the way of reliable comparisons if certifying practice and the form of the medical certificate still varied. A signal achievement lies in the van of measures directed toward the adoption by all countries using the *International List*, of questions relating to cause of death which are either the same or essentially similar in character.

The existence of so many different types of questions in the medical statement of cause of death the world over bespeaks dissatisfaction with probably most of them. Dissatisfaction in Canada was general long before the study of the phraseology of the medical questions was initiated in 1933. In France, Germany, and Holland only "cause of death" is requested, and it is not intimated that more than one entry would ever be appropriate, nor is instruction given for the certifier's guidance in selection of that single cause. In Japan the certifier is specifically instructed to make only a single entry, but instructions for his guidance are given. There is no evidence, however, that the physician has intelligently applied his instructions and, furthermore, there is no possibility of tabulating more than one cause.⁴ In Canada until 1935, and in the United States until 1930, two questions were included, namely: "Cause of Death," and "Contributory (secondary) Cause." In England and Wales until 1927 the form called for

"Cause of Death" and "Secondary (Contributory) Cause."

In Sweden the form provides for principal and contributory causes, suggesting that in some cases it may be appropriate to indicate more than one cause, the interrelation being one of importance. The relationship most frequently called for in other countries is one of causation, but prior to the revision of the medical certificate in the years noted above in England and Wales, the United States and Canada, the forms called for statements of causal relationship and then obscured the issue by indicating that the statement might alternately be one of importance. Thus relationship of causation and importance were thoroughly confused.

When multiple causes are stated, two relationships between jointly stated causes of death, namely, of importance and of causation, are of interest to those tabulating returns. The medical certificate used in Switzerland (Figure III) illustrates this in making provision for (a) primitive disease or primary cause, (b) consecutive disease and immediate cause, and (c) contributory diseases or circumstances worthy of mention.

From the physician's point of view the form of the questions should be logical and convenient to his memory, and *from the statistician's viewpoint*

CAUSE OF DEATH	
<i>Principal Cause</i>	1.
Immediate Cause	due to
Causes antecedent to above in order of relationship	2.
	due to
	3.
	due to
Independent contributory causes, if important (not causally related to principal cause)	4.

FIGURE I

should clearly separate those causes which are related and those causes which are independent of the disease responsible for death and to which death should be attributed.

DEVELOPMENTS IN RECENT YEARS

The report of the committee entrusted with the Study of Causes of Death in its report to the Health Organization of the League of Nations in 1925, suggested the certificate reproduced in Figure I.⁴

Immediate principal cause was defined as the morbid condition actually causing death, and causes antecedent to it, any others of which it was the consequence. If multiple causes were recorded, the order of relationship would be indicated thus: (1) broncho-pneumonia, (2) measles; (1) acute peritonitis, (2) intestinal perforation, (3) typhoid fever. This form begins at the proximal end of the train of causation rather than at the "primary cause" and thus assures a statement of the cause required for tabulation.

The committee indicated that in most instances it would be sufficient to state the principal cause, "reserving statement of contributory causes for instances where the deceased succumbed to a combination of maladies none of which would necessarily have been fatal alone." In such cases the certifier's judgment alone can indicate

the cause which should be selected for tabulation.

The present difficulties and present statistical practices arise largely because the information for making an intelligent selection for tabulation is not obtained from the certifier. It is therefore necessary to substitute certain general rules which may or may not apply in any given case. This form, as can be readily seen, establishes both the relationship of importance and of causation, and provides an opportunity for the physician to set forth clearly his opinion. It would appear to make it possible to dispense almost entirely with rules of selection and ultimately to form simple rules, in each case based on the certifier's opinion as expressed in his statement.

It is noteworthy that in 1927 a medical certificate similar in outline to that suggested in the committee's report was introduced in England and Wales (Figure II). Following the introduction of this form, selection according to the usual plan was continued, but late in 1935 it was recommended that beginning in 1941 the selection of the causes of death for tabulation be based on the certifier's viewpoint as expressed on the certificate, in place of selection by rule.⁵ Thus it has been shown that the new form of statement is a satisfactory one and that this, the original objective, first despaired of,⁶

CAUSE OF DEATH	
I	
Immediate cause *	(a) due to
Morbid conditions, if any, giving rise to immediate cause (stated in order proceeding backwards from immediate cause)	{(b) due to (c)
II	
Other morbid conditions (if important) contributing to death but not related to immediate cause.
* This does not mean the mode of dying, such as, e.g. heart failure, asthenia, etc.; it means the disease, injury or complication which caused death.	

FIGURE II—ENGLISH FORM

(b) Consecutive disease and immediate cause of death
(c) Contributory diseases or circumstances worthy of mention

FIGURE III

will be achieved within 15 years of the introduction of the new certificate. It would appear, therefore, that the recommendation of the Commission revising the *International List* in 1929³ is possible of achievement, namely: "that the certificate of death should be planned so as to show as exactly as possible the opinion expressed by the physician on the cause or causes of death in each individual case, and to limit as much as possible the selection by the Central Bureau entrusted with the classification of the cause of death."

As the certifier is given a free hand to trace the pathological history of his patient, some will push this matter much further than others. Some will be satisfied with recording cerebral hemorrhage as the cause of death; others will record arteriosclerosis as the cause of the hemorrhage; and still others may mention the septic or other cause to which they attribute the arteriosclerosis. The international adoption, in principle at least, of such a certificate as that proposed by the League of Nations Study Committee cannot, therefore, be expected to dispense completely with the need for agreement on certain points of detail. Such deaths are all essentially similar in nature and should be grouped to-

gether. It would not do to assign some of them to cerebral hemorrhage, others to arteriosclerosis, and others to the condition recorded as the cause of the arteriosclerosis. It would be necessary to agree upon the point at which such chains of causation should be severed for statistical purposes.

International agreement should be easier to attain in respect to such conventions than upon rules of selection such as we now have. Today, we assume that we do not know what the physician's opinion is regarding the relative importance of the causes stated and classification carried on in this fashion necessarily leaves much room for differences of opinion and criticism.

CANADIAN EFFORTS

In 1935 a new form of medical statement was introduced in Canada. This is almost identical with that adopted in England and Wales in 1927 and is therefore similar to the form recommended in principle for international use by the group reporting to the League of Nations in 1935⁴ and to that adopted by the Commission Mixte de Statistique Sanitaire of the International Statistical Institute at Cairo in 1928.

Before this change was made, the

The principal cause of death and related causes of importance were as follows:	Date of Onset
.....
Other contributory causes of importance:
.....

FIGURE IV—UNITED STATES STANDARD FORM

Committee on the Form of the Medical Certificate of the Canadian Public Health Association undertook a careful survey of the phraseology of the questions relating to cause of death in use throughout the world. The English form (Figure II) and the Swiss form (Figure III) both represent attempts to secure a logical statement and a clear separation of contributory causes which are related to and those independent of the disease to which death is attributed for statistical purposes.

The phraseology of the United States standard medical certificate was also investigated (Figure IV) in a series of trials conducted by the committee.

In addition to these and numerous other types of phraseology for the questions relating to cause of death, the committee prepared several drafts of its own. The first of these was the Minnesota certificate with the addition of a line for "terminal cause." The second is shown in Figure VI, and represents an attempt to place the burden of classification directly upon the physician. In a third draft the words "independent of underlying cause" were added to the request for a statement of "Contributory causes of importance."

It is noteworthy that the modifications made by the committee in each case moved toward the objective served

The Primary Underlying Cause of Death was	Duration
Contributory causes of importance in order of onset	Duration
(1).....
(2).....
(3).....

FIGURE V—MINNESOTA FORM

The medical certificate used in Minnesota differs from the United States standard chiefly in the request for a statement of "Primary Underlying Cause." and in asking duration rather than date of onset (Figure V).

by the English form of statement. Thus each revision attempted to do two things: (1) to establish more clearly the certifying physician's opinion, and (2) to separate effectively contributory causes which were related to the "cause

CAUSE OF DEATH

of death," from other morbid conditions contributing to death but which were of independent origin.

COMMENT ON THE FINDINGS IN CANADIAN TRIALS

In trials of the English and United States forms conducted prior to other investigations it was found that physicians preferred the English method of statement and the logical order which it called for. Trials with the drafts prepared by the committee, referred to above, were only moderately satisfactory. The additional weight which was placed on the entry of a terminal cause was found to be unjustifiable since this was usually of no significant assistance in classification. Where a single entry was made, this was often entered as the terminal

cause, the space for primary underlying cause being left blank. Having allowed three lines for the primary underlying cause, multiple causes were frequently stated there, obscuring the physician's opinion and defeating the objective.

Finally a field trial was undertaken in 8 large hospitals, using the English form with minor changes in wording⁷ and the final (fourth) draft prepared by the committee, shown in Figure VII.

The findings of this latter undertaking emphasized the fact that whatever form was introduced, education would be a large factor in getting physicians to use such a form properly, and that *after the medical questions were changed there would undoubtedly be a period of transition during which physicians would continue to use it as*

CAUSE OF DEATH	
I	(a) Bronchopneumonia
Immediate cause	
Give disease, injury or complication which caused death, <i>not</i> the mode of dying, such as heart failure, asphyxia, asthenia, etc.	due to

	{

FIGURE VIII—NEW CANADIAN CERTIFICATE OF CAUSE OF DEATH

if it were the old one. This has been borne out by experience during 1935 and 1936. In addition the studies demonstrated conclusively that, given the logical form of statement called for on the English medical certificate, the tabulator was provided with a better picture of the case and with more useful information to assist him in classification.⁷ It was for this reason and in view of the recommendations made to the League of Nations as well as those of the Commission revising the *International List* in 1929, and also in the light of the experience in England and Wales, that Canada introduced in 1935 the new form of medical certificate of cause of death which it now has (Figure VIII).

The new English and Canadian certificates are designed to eliminate personal bias by reversing the order of statement, calling for the immediate cause first and then others in order, making provision separately for any unrelated causes considered by the physician to have been important contributing factors in the death.

The present procedure in certification in Canada may be stated briefly thus: If the physician feels that his

case can be adequately certified by a single statement, this is entirely satisfactory. Such a statement is made under heading I, on the first line designated (a). If, however, such is not adequate, he has the opportunity of recording further information, either on lines (b) and (c) under heading I, or under II, according as the conditions to be recorded are respectively of related or independent origin in so far as the first statement on (a) is concerned. This information is sought to permit the selection of the cause for tabulation in the light of the certifier's viewpoint.

EXPERIENCE WITH CANADA'S NEW FORM

During the first 6 months after the introduction of the new form in Canada, as in England 8 years before, both the request for concise statements, and the fact that the order of statement was inverted from the old form, were disregarded by many physicians. Since that time there has been notable and persistent improvement. Table I gives the findings on the use of the new form at two intervals after its introduction in 1935.⁸ The findings in an English sample⁵ reported

TABLE I
*The Use of the New Canadian Medical Certificate**

Type of Entry	Toronto ¹		Toronto ²		England & Wales ³	
	Number	Per cent	Number	Per cent	Number	Per cent
Single entry	110	12.2	274	28.0	5,637	57.0
Multiple entry in reasonable order and without ambiguity	548	61.1	504	51.4	4,001	40.5
Inverted entry †	240	26.7	172	17.5	107	1.1

Totals	898	100.0	980	100.0	9,892	100.0

* Samples exclude stillbirths.

1. Samples taken May-August, 1935, 6 months after introduction.

2. Sample taken March-April, 1937, 25 months after introduction.

3. Sample taken March, 1935, after 8 years' experience (after Stocks).

† Multiple causes in incorrect order or location, obscuring physician's viewpoint.

‡ Two causes or more stated on one line and therefore ambiguous.

by Stocks are given for comparison.

A reduction in the number of multiple entries and a corresponding increase in single entries is of note. A reduction in the proportion of misused forms (inverted and double entries) is also gratifying. Indeed, the general consensus in Canada is that the new form represents a decided improvement over the old one and that the former confusion is being replaced by a clear statement of the opinion of the certifying physician. The younger physicians are using the form well, while those long in practice and accustomed to the old methods still frequently disregard the request for a logical sequence when multiple causes are stated.⁹ This augurs well for achievements such as have been already sighted by the English office.

DATE OF ONSET OR DURATION ON THE MEDICAL CERTIFICATE

In respect to the need for date of onset or duration on the medical certificate the general opinion in Canada⁹ is that such should not be included, particularly since it is used merely to assist in making decisions when the medical certificate is unsatisfactory. In very few instances does the record of a communicable disease contracted at an earlier date leave doubt as to classification, and such cases in view of their infrequency may readily be handled by supplementary correspondence with physicians. In just those cases in which the principal difficulty in classification arises (due to faulty certifying practice) duration is often not given, and, if given, is less likely to be reliable. For these and other reasons it was omitted from the revised form. Furthermore, the objective of the new certificate is to place the burden of indicating the cause of death for classification on the physician and not on the statistician. The difficulties which are now being experienced,

arise chiefly from conflict in the application of rules of choice where joint causes are stated.

STATISTICAL PRACTICE—RULES OF CHOICE IN JOINT CAUSE SELECTION

More faith is often placed in statistics on causes of death than is justified. An analysis of the principles upon which they are based convinces one of the serious limitations inherent in them. The medical profession is somewhat skeptical of official records of causes of death and cannot be blamed entirely for this attitude. Physicians who are cognizant of statistical practice object to the way in which their medical statements are distorted in the official routine. They feel that it does not make much difference what form their statements take, since the death of their patient is frequently attributed to a cause with which they would not agree.

Rules of choice are designed to secure the uniform selection of a single cause where joint causes are stated or in other words to counteract the effect of ambiguous or unsatisfactory death certificates. The need for them arose largely because physicians did not understand the meaning of "cause of death" for statistical purposes, and because the phraseology of the medical questions in many countries was not based on establishing clearly the "cause of death" as defined. Failing to understand what is desired officially, physicians cannot hope, nor can they be expected, to give clear and unambiguous statements for the tabulator's guidance.

Under these circumstances and in the belief that "some physicians all of the time and all physicians some of the time" would attribute major importance to a complicating condition or end result rather than to the underlying disease, a set of arbitrary rules of choice has been laid down for use except when

there are other qualifying words or phrases such as "due to" or "following" on the medical certificate, which in themselves may lead the statistician to infer a contrary ruling. This practice is quite unscientific, from the medical point of view distorts the facts, and may at best be regarded as an unsatisfactory makeshift.

WHAT DO OFFICIAL RECORDS OF CAUSES OF DEATH TELL US NOW?

The net result of the use of arbitrary rules of practice deserves careful examination. On a certificate containing two questions, (a) "Cause of Death," and (b) "Contributory Causes," it would not matter whether appendicitis or peritonitis was recorded as cause or as a contributory, since the rules give preference to the primary diagnosis. What of a case of diabetes in which tuberculosis coexists? Rules of choice give preference to tuberculosis, but actually no rigid rule can be relied upon to interpret these cases correctly for the doctor. No two of these cases are of necessity alike. From the clinical viewpoint diabetes might be the "cause" in one case and tuberculosis in the other. Unless it is desired that records of cause of death become records of the incidence of certain diseases among the population at death, arbitrary rules like the above have no scientific support, and, furthermore, they place a premium on records of certain morbid conditions to the defacement of others.

The necessity for the adoption of such rules of selection therefore arises solely out of a system of certification "under which a number of concurrent or contributory causes are stated without complete or adequate guidance from the certifying medical practitioner as to the causal relation between them." The usefulness of any code of rules applied in making assignments would be greatly modified if it could

be provided that "the certificate should itself contain such indications as would enable the selection to be determined by the practitioner's own considered judgment."¹⁰

This the English method of statement has been found to do, and there is no reason to infer that experience in Canada or elsewhere need be materially different if a similar form be used. The Conference at Paris in 1929 did not recommend the establishment of a general international code of rulings for dealing with joint causes. Indeed certain countries there represented felt "that the establishment of a rigid code for the classification of joint causes, however carefully elaborated, may have the effect of retarding the process of improving the quality of the entries in the certificates themselves, and to this extent would be undesirable."¹⁰ The achievements in respect to certification in England strongly suggest the immediate need for serious thought to be given by other countries to the methods and objectives adopted there.

The rigid principles of joint cause selection tend to prevent official records of causes of death from being a sensitive index of medical achievement. Diabetes and cancer are two illustrations. Let us consider this point, keeping in mind that official records should reflect in so far as is possible, the considered opinion of an enlightened medical profession on the diseases which are fundamentally responsible for death.

DIABETES

In 1936 a confidential study of all deaths in which diabetes was mentioned on the death certificate in Ontario during a 12 month period, was undertaken in the School of Hygiene at the University of Toronto.¹¹ It became evident that no uniform arbitrary scheme for the selection of one cause

TABLE II
*Classification of 602 Deaths
 Among Diabetics
 Ontario, 1935*

<i>Physicians' Opinion</i>	<i>National Practice *</i>		<i>Total</i>
	<i>Diabetes</i>	<i>Other Causes</i>	
To diabetes	218	22	240
To other causes	213	102	315
Not stated	40	7	47
Total	471	131	602

* Except diabetes preferred to lobar pneumonia.

The General Register Office in London, England, in 1935 reported upon a small sample of 121 medical certificates assigned to diabetes under statistical rules.¹² Of these 42 contained a statement of diabetes alone and 79 multiple causes. If the order of preference indicated on the certificate had been followed, 30 of the latter would have been assigned to other causes, giving 91 diabetic deaths or only 75 per cent of the original total. At the same time an inward transfer of 5 deaths would have occurred from other causes—a net loss of one-fifth. These data show that present practice fails to reflect accurately medical opinion.

CANCER

It is generally conceded that official statistics on cancer as a cause of death present errors in excess. The extensive preference given to cancer over other jointly stated causes has served to provide more nearly a statement of the incidence of cancer among the population at death than a measure of the mortality attributable clinically to this cause. Merely because an individual has a cancer, particularly if it is one of the accessible group of sites amenable to surgery, radium, X-ray, or a combination of these, is not sufficient reason why rigid preference should be given to it over causes of in-

dependent origin. Because cancer was present in the patient at death is not sufficient justification for attributing that patient's death to cancer.

Part of the solution to this particular difficulty lies in a medical statement which permits the physician to indicate clearly his own opinion and to say whether he thinks cancer was the important factor in death. *If it did not contribute to an important extent it should not be mentioned on the death certificate at all.*¹³

It has been urged that internationally uniform rules of preference where joint causes are stated would be a step toward comparability of records of causes of death on an international basis. This is an illogical contention since it implies that this in itself is the major source of the basic differences which now exist. There are many illustrations of incomparability traceable to this factor of course, but unless fashion of certification, unless the medical profession in various countries are informed upon the principles of medical certification, and unless the medical certificates are identical or essentially similar in plan the world over, international comparability of records will remain the myth it is today.

DISCUSSION

Many factors influence the completeness and accuracy of medical statements of cause of death. Of these, the form and phraseology of the questions relating to cause of death are ones whose influence upon the physician's report has been inadequately considered.

To define "cause of death" for the purpose of medical records as the "disease or injury which initiated the train of events leading to death" and to tabulate all records in the light of this definition is a major step toward securing sound practical information, if cognizance be taken of medical

opinion. Any attempt to make mortality records reflect disease incidence, and arbitrary rules in joint cause practice tend to do this, is open to objection and to failure because the viewpoint of the attending physician in many cases has to be disregarded and because mortality data can never serve as a reliable index of the incidence of disease among the population at death.

The history of attempts to improve medical certification is a history of attempts to find a means of making clear to the physician what is desired and to secure his full coöperation. Given a clear definition of the purpose of mortality data and an understanding by everyone of the significance of "cause of death" for statistical purposes through educational efforts which include the certifying physician, the problem resolves itself into one of phrasing the medical questions so that ambiguity is eliminated.

Completeness of medical statements is of secondary importance to accuracy. Accurate statements are ones which are adequate to give a clear expression of what "caused" death. A medical statement can be accurate and adequate for this purpose and yet, in the minds of some, be quite incomplete. Completeness should be considered as something ideally useful, virtually unattainable except in hospital experience, and, from the practical viewpoint, of little concern at the moment.

For many years we have pointed with pride to the declining proportion of deaths classed to "Cause of Death Not Specified or Ill-Defined." This pride is unjustifiable since this trend is in some measure due merely to the fact that physicians have been made to feel that in all deaths due to natural causes some specific statement *must* be given. They therefore often make statements which they have no evidence to substantiate. It would be far better to encourage physicians to state "cause

unknown" or "unknown disease" when they find it impossible to make a scientific statement.^{14, 15, 16} Statistics on causes of death could be much improved if all deaths for which the cause could not be reasonably well determined by the physician were so specified and so classified. Better to have 10 times the number of deaths classed to "Cause Unknown or Ill-Defined" than to have them included under headings where they very likely do not belong at all.

The question of the most desirable and satisfactory phraseology for the questions relating to cause of death on the medical certificate, is one of supreme international as well as national importance. We cannot afford to ignore the broad implications involved. Less stress on statistical rules and their uniformity and more on securing the certifier's viewpoint, is what we need today.

SUMMARY

1. Three aspects of medical certification deserve consideration, namely, education of the medical profession in the principles and practice of death certification, the form of the questions relating to cause of death, and the statistical practices to which medical statements are subjected in tabulation.

2. The achievement of accurate medical statements which reflect the considered opinion of the medical profession is an urgent need and depends first upon the physician clearly understanding the significance of the questions relating to cause of death and the general principles of death certification, including a clear conception of what is meant by "cause of death" for statistical purposes.

3. A lasting service to preventive medicine can be performed by each physician who produces authoritative and logical certificates of cause of death, and time should be found in the curriculum of medical schools to impress the essential points upon each student.

4. Satisfactory phraseology of the medical questions must fulfil two requirements: (a) give the physician the opportunity to express clearly his opinion as to the cause of death in each case, and (b) effectively separate contributory causes which are related to the disease causing death from those which are

considered to be contributory factors but independent of the underlying cause of death.

5. English experience has conclusively demonstrated the workability of a form which fulfils all the requirements which are necessary to an intelligent statistical assignment. Beginning in 1941, selection of the cause of death for tabulation is to be based on the certifier's opinion as gathered from a literal reading of the certificate, in place of selection by rule.

6. The existence of so many different types of phraseology of the medical questions the world over is in itself a serious source of incomparability of records on an international basis, and significant progress in this direction will be attained with the achievement of a uniform program for the medical certificate in all countries using the *International List of Causes of Death*.

7. Canadian experience since 1935 with a new form of medical statement similar to that introduced in England and Wales in 1927, as well as to that suggested by a group reporting to the Health Committee of the League of Nations in 1925 and subsequently by the Commission Mixte de Statistique Sanitaire of the International Statistical Institute at Cairo in 1928, has been gratifying and augurs fair for achievement of the objective of being able to accept the certifier's viewpoint in place of selection by rule.

8. A request for duration should not be included on the medical certificate among other things because (a) in many instances it is not reported upon and even when it is there is no plausible guarantee of accuracy, (b) the importance attached to it through assignment based on relative durations is merely a makeshift, failing a reasonable statement of medical opinion on the certificate, and (c) the ultimate objective, if scientific records of the causes of death are to be compiled, must be to place the burden of indicating the cause of death for tabulation upon the physician and not on the statistician.

9. Existing statistics on causes of death have serious limitations, traceable to the application of arbitrary rules under which they can never succeed in reflecting medical opinion. This they should be expected to do, and indeed must do, if any real significance is ever to be attached to them in practice.

10. Diabetes and cancer are just two instances of inaccuracies resulting from the rules of joint cause selection. Present methods tend to make statistics of causes of death a measure of the incidence of such diseases

among the population at death, understating certain others as a result.

11. Existing practices are shown to lead frequently to an assignment with which the physician would not agree. *Part of this difficulty may be attributed to lack of appreciation by physicians as to what is desired on the form.* Many seem to regard it as a place for an abstract of the clinical history and pathological findings, which it certainly is not. What is desired is a terse scientific statement of the disease or condition responsible for death. Only important states should be mentioned, and while it appears to be implicitly thought that this is uniformly observed by the profession, nothing is more certain than that it is not. *If a disease or condition is clinically not an important contributor to death it should not be mentioned on the certificate at all.*

12. Anything approaching complete international agreement as to a uniform code of rules for the selection of one cause for tabulation where multiple causes are stated can never achieve anything of fundamental value toward international comparability of mortality statistics. Unless the medical profession be properly educated and instructed in the use of the medical certificate and unless medical certificates are similar in plan the world over, international comparability of medical records will remain the myth it is today.

13. Less stress on statistical rules and their uniformity and more on securing the certifier's viewpoint should be a guiding principle in the future.

14. The question of the most desirable and satisfactory phraseology for the questions relating to cause of death on the medical certificate remains still the important problem of the moment, and one of supreme national as well as international import.

Deadliest Drivers Are Boys

DEATH behind the driver's wheel, in the terrible annual auto accident toll, is not a grim, old, bearded man with a scythe. He wears the beardless face of a boy. Flaming youth at the wheel is the deadliest foe of today's highway-using public.

Remorseless statistics, presented before the American Association for the Advancement of Science by a critically analytic scholar, prove the indictment beyond possibility of denial. Dr. Harry M. Johnson, who led the study under the auspices of the Highway Research Board, sums up the case briefly and dramatically:

"If we pick the same number of drivers in each age group, and count the fatal accidents that each group has,

we find that those who are 45 to 50 years old kill the fewest persons in a year. While they are killing 66, the 16 year olds are killing 201, the 17 year olds 186, the 18 year olds 148, and those between 19 and 21 are killing about 215 persons for each 100,000 drivers on the road. . . .

SECOND DANGEROUS AGE

"The drivers older than 45 tend to become more deadly each year, reaching the average rate for the whole population about age 64 to 65, whereupon the rate suddenly falls. This decline may be due to the older drivers driving less and less, instead of better and better."—Dr. Frank Thone, *Science News Letter*, March 5, 1938, p. 150.

Organisms Involved in the Pollution of Water from Long Stored Feces*

LELAND W. PARR, PH.D.

*Department of Bacteriology, Hygiene and Preventive Medicine,
School of Medicine, The George Washington University,
Washington, D. C.*

OBVIOUSLY one of the most important factors controlling the flora of stored feces is the bacterial picture of the feces before storage. The complexity of this original flora is almost beyond belief. Of the many microbes present only those of interest to pathology or others which may serve as indicators for fecal pollution are at all well known. Omitting frank pathogens from consideration, fresh fecal specimens may contain coliform bacteria, enterococci, classical anaerobes, non-sporing anaerobes, yeasts, spirochetes, staphylococci, lactobacilli, thermophilic bacteria, aerobic spore-bearers, *Pseudomonas*, and reputedly even the "Bacillus P" of Clemesha,¹ molds, algae, *Proteus*, *Alcaligenes*, and Friedländer's bacillus. The "invisible" viral content of the bowel can only be guessed at and in its environment bacteriophage activity may be considerable.

Again, it is now well recognized that the flora of the individual differs from time to time even when that individual is in normal health and on a relatively stable diet. Occasionally no coliform bacteria can be detected, and at other times though coliform organisms may

be present *Bacterium coli* in all its varieties may be absent, the only group organisms present being the citrate-utilizing *Bacterium aerogenes* or coliform intermediates (Parr^{2,3,4}; Carpenter and Fulton⁵). Bailey⁶ has reported a colon carrier of typhoid bacilli yielding practically a pure culture of *Eberthella typhi* and Sandholzer⁷ a case in which the only organisms recovered were *Pseudomonas*. Parr⁸ has recorded one subject in whom only chromogenic colon bacilli were present and another in whom the sole aerobic fecal flora was paracoli. Some years ago Van der Reis⁹ had a patient with a secondary anemia from whom a practically pure culture of *Clostridium tetani* was recovered.

Thus we know that fresh fecal specimens may be encountered which can pollute water without detection by the bacteriological methods now in use. Happily such specimens are not common and probably figure very little in sanitary problems involving communities. Nevertheless, even in modern society, many factors still operate for the individual pollution of food and drink and, indeed, in recent years there has been an increase in such opportunities through the rise of a large transient population, improvident and otherwise.

As long as bacteriologists can be

* Read before the Laboratory Section of the American Public Health Association at its Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

satisfied that all outbreaks of gastrointestinal distress, transmitted by water, are caused by well known and clearly recognized pathogenic forms of enteric bacteria one might suppose but little need exists for detailed study of the flora of feces, fresh or stored. Such is not the case. No aspect of bacteriology offers a better field for studies in bacteriological ecology, in the origin and interrelation of bacterial species, and in microbic genetics than does intestinal bacteriology. Sanitarians pose questions of great practical importance regarding indices of pollution, recent pollution, human versus animal pollution, and the like which are still unanswered. There is no bacteriologist who has not been impressed by the fact that within a few hours following the drinking of sewage polluted water illness appears which may or may not later be followed by cases of amebic dysentery or typhoid fever. What bacterial component of the sewage causes the earlier aspects of this well known phenomenon, and how?

Again, from time to time, bacteria are reported as causes of disease whose exact nature or place in the intestinal flora is not clearly understood; for example, "*B. coli mutabile*," slow-lactose fermenters, "*B. alkalescens*," Morgan's bacillus, and paracoli. Finally, sanitary science is increasingly meeting with cases of individual or mass disease, apparently water-borne, for which no etiological agent can be named, and occasionally when the water in question, by present standards, appears to be potable.

In the endeavor to obtain a better understanding of these problems we have been led to consider the part bacteria from stored feces may play. This interest has been accentuated by studies of the 1930 and 1931 records of illness in the Ohio Valley during widespread drouth and by the implications arising from our studies on the

normal flora of fresh and stored feces in the human.

That long stored feces will contain bacteria different from those encountered in a study of fresh feces should be evident from an appreciation of the principles of ecology. For fecal specimens, protected during storage from admixture with non-fecal bacteria, the new bacterial picture can be explained on two different grounds.

It is possible that some of the bacteriological changes observed may be due to bacterial variation—the loss of characteristics or the acquisition of new ones apparently giving rise to new organisms. This may be the origin of slow-lactose fermenters, "*B. coli mutabile*," or even paracoli from *Bacterium coli*.

On the other hand most of the evidence suggests that the bacteriological changes observed as fecal specimens are stored are to be explained as successions of forms based on facility of adaptation to the environment presented under conditions of storage. The first real study of the effect of storage on feces was made by Jordan,¹⁰ who utilized fecal masses stored in tight containers. Some of the masses were uncovered and others were covered with soil or with sand. Four temperatures were used—body, room, ice box, and —11° C. Jordan found that when feces leave the body there is a short period of multiplication of the bacteria they contain, later followed by a numerical depression. This takes place at all temperatures but is most rapid at the temperature of the body. This was explained on the theory that in the bowel some sort of inhibitive factor operates which is absent from the excreted feces. Jordan did not analyze the bacteria involved in any great detail but he did determine that the multiplication he observed was not that of *Bacterium coli* but of other bacteria present in the feces. *Bacterium coli* is

eventually eliminated from stored feces, most rapidly at body temperature, most slowly at -11°C . At this last temperature Jordan found that coli persisted for 2 or 3 months.

In this paper we shall discuss but two of the bacterial groups important in feces. For more than 4 years we have been studying the normal flora of fresh and of stored feces in the human subject. During this period 235 specimens from 100 persons have been studied in some detail. Thirty-eight of these specimens have been studied stored at 37°C ., and more than half have been stored in the cold room with storage studies completed on 68. The feces were stored as heavy saline suspensions. Endo's agar was used for direct plating, the 38 body temperature storage specimens being plated 183 times, and the 68 from the ice box 368 times. With a very few exceptions the 37°C . and ice box storage specimens are duplicates prepared from the original fresh specimen on which study of the flora of fresh feces was made. Enrichment by lactose broth followed by plating was only used where adequate direct plating failed to yield growth.

The 2,595 colonies isolated in these 551 platings were carefully purified and subjected to detailed pure culture study. Results were recorded in terms of coli, coliform intermediates, and aerogenes through utilization of the four tests comprising the "Imvic" reaction,² namely indol production, methyl-red reaction, Voges-Proskauer reaction, and citrate utilization. A number of other determinations were made for each culture and form a part of the complete record.

We early found that about 9 per cent of all fresh fecal specimens studied to determine their coliform content contained only *Bacterium coli* in one or more of its fermentative varieties. It is true that the original routine analysis of the fresh specimens

revealed about 3 times this number of "coli only" specimens. However, by unusually detailed study of the fresh specimen or by following it carefully through storage, two-thirds of these were found to have originally contained a few citrate-utilizing coliform bacteria which as storage progressed developed at the expense of the coli and dominated the coliform picture after a few weeks of storage.

For the coliform bacteria there are then two pictures to be seen in stored feces. When the original fresh specimens (9 per cent) contain only *Bacterium coli*, no amount of storage will bring about the presence of any other type of coliform organism. Specimen No. 4 illustrates the point. In ice box storage this specimen yielded coliform bacteria for 359 days. During this period it was plated on Endo 22 times and 124 colonies were given pure culture study. Each culture was *Bacterium coli* and even the last isolations appeared on Endo and in culture as "typical" colon bacilli. Similar results were obtained with specimens Nos. 57A, 88, 92, 95, and 118. These 6 specimens were obtained from 5 different subjects. It is thus possible for a stored fecal specimen to yield "typical" *Bacterium coli* for a very considerable time. It is important to realize that in such specimens *Bacterium coli* persists despite considerable competition offered by other bacteria present in the specimen which are not coliform, such as enterococci, spirochetes, classical anaerobes, and *Bacteroides*. *Bacterium coli* cannot, therefore, be unqualifiedly considered as the indicator of recent fecal pollution.

The more common picture as far as coliform bacteria is concerned is observed when the original fecal specimen contains citrate-utilizing coliform bacteria as well as *Bacterium coli*. The citrate-utilizers (aerogenes, cloacae, coliform intermediates) multiply in

storage very much more readily than do the coli, and eventually completely replace them. Along with this change we observe an increase in the proportion of strains which ferment lactose slowly or with acid production only, and an increase in gelatin liquefiers.

Such specimens will not number 91 per cent for we have found that in any large series of fresh fecal specimens there will be some from which no coliform organisms can be isolated. Thus among 194 such specimens from adults 4 were encountered deriving from 3 persons which failed, even with enrichment, to yield coliform organisms, and there were 7 specimens likewise coliform negative among 41 specimens obtained from normal babies less than 2 weeks old.

Recovery of coliform organisms can be made after long intervals of storage of fecal specimens in the vast majority of instances. Parr¹¹ has elsewhere discussed the viability of coliform organisms in culture and in other environments. One further illustration will clarify the point and extend his earlier remarks. Specimen No. 3, as a fresh specimen, on direct plating yielded only *Bacterium coli* (15 colonies studied). Under conditions of storage in the ice box the coli diminished in number and citrate-utilizers appeared ultimately pushing the coli completely out of the picture. When last plated out this specimen still yielded citrate-utilizing coliform bacteria after an interval of storage amounting to 3 years, 10 months and 2 days. The period of survival is shortest at 37° C. and longest when the suspension is stored in the cold. Among the coliform types noted in such long stored fecal specimens are some similar to, if not identical with, slow-lactose fermenters, "*B. coli mutabile*," "*B. coli anaerogenes*" and even the "*B. alkalescens*," and paracoli mentioned in some connections as pathogenic.

The second bacterial group to which a short preliminary discussion will be devoted is that which goes for the time under the name "*Bacillus P.*" In India, Clemesha¹ was convinced that it was next to impossible to obtain water for drinking purposes which would meet British standards. He proceeded to work out a method of bacteriological control applicable to the climate and conditions of India. He proceeded on the hypothesis that some strains of coliform bacteria might be more indicative of fresh fecal pollution than others. To find which these were he prepared suspensions of feces which he exposed in shallow dishes to the action of sunlight. Isolations were made at short time intervals. Clemesha found that certain forms could be recovered from fresh feces and for a few hours from the exposed suspensions. These were, however, shortly replaced in the suspensions by other forms, and these in turn by yet others, until at last all lactose fermenting aerobes had disappeared. There then remained Gram-negative, non-sporing aerobes which he called "*Bacillus P.*" Beyond noting their resistance to the action of sunlight under the conditions of his experiment, Clemesha did nothing with these forms save to suggest that they were probably a group of bacteria and not a single species.

In our study of stored fecal specimens we have encountered these organisms. After a few weeks of storage they begin to appear and in most long stored fecal specimens "*Bacillus P.*" occur in large numbers. When plated on Endo they grow as small, colorless colonies. The organisms exhibit a variety of biochemical activity, are in the main motile, and do not produce acid and gas from lactose even after repeated and prolonged incubation. All of the group in colony appearance, and some in culture, resemble paratyphoid, typhoid, and dysentery bacilli

and may be mistaken for them. Furthermore, certain of the strains give serological cross-reactions with these known enteric pathogens. Possibly the "Bacillus P" may be involved in gastroenteritis, apparently water-borne, since organisms similar to those we have under study have been reported from such outbreaks.¹²

Parr and Caldwell¹³ encountered similar organisms in great numbers in water deriving from wells yielding old fecal pollution as shown by chemical tests. Parr¹¹ again mentions them in a study on the viability of coliform bacteria and elsewhere³ he states they may occasionally be found in small numbers in fresh feces.

Data are available for 35 strains of the "Bacillus P" which we have isolated from long stored feces stored in the cold and in a few instances from fresh feces. The strains were purified by repeated plating and were then subjected to detailed pure culture study. From 6 strains, examples of different cultural types, antisera have been prepared. Of the 35 strains 11 do not ferment any sugar. Eighteen strains produce acid but no gas in dextrose broth, and of these, 7 also ferment lactose to the same degree, but are not in colony appearance or in other reactions suggestive of "*B. coli anacrogenes*." Six strains ferment dextrose producing both acid and gas. Two strains produce hydrogen sulphide and 6 liquefy gelatin. Of these last one is a typical *Proteus* but the other 5 are not. The "Imvic" reaction (vide supra), which is applied to coliform bacteria divides the 35 strains into 5 groups (— — — +, — — — —, + + — —, — + — +, and — — + +), but these divisions do not correlate with fermentation and other cultural differences.

Five of the antisera prepared with these organisms have been tested against 10 appropriate known strains—

E. typhi, *S. sonnei*, *S. paradysenteriae*, *S. paratyphi*, *S. Schottmuelleri*, *S. enteritidis*, *S. cholerae* suis, *S. aertrycke*, *Proteus X₂*, and *A. fecalis*. No relationship was shown for Sonne's dysentery bacillus but cross-reactions occurred for *E. typhi* and *S. paradysenteriae*. Several of the strains suggest *Alcaligenes fecalis* culturally but the serum with one of them gave only a feeble agglutination reaction with a known *Alcaligenes fecalis*. Strongest cross-reactions were obtained with the human types of *Salmonella* against our serum No. 2, prepared with one of the "Bacillus P" organisms culturally resembling paratyphoids. Against a known *S. paratyphi* this serum effected complete agglutination in a dilution of 1/320, the titer of the serum with its engendering organism being 1/5120.

Such reactions mean no more than some degree of common antigenicity, but are sufficiently suggestive to warrant interest in the "Bacillus P" organisms. The group may have some sanitary significance, particularly under conditions permitting fecal storage in nature. It is possible that "Bacillus P" may be the group involved in the multiplication of bacteria in stored feces indicated by Jordan. Certainly their taxonomic position should be investigated and their relationship to the colon-typhoid groups clarified.

CONCLUSIONS

Some of the principles and theories underlying the development of a fecal flora in stored feces are discussed. Data derived from a study of 2,595 coliform colonies isolated from platings of stored feces permit a statement of the part played by the genus *Bacterium*. The "Bacillus P" of Clemesha is discussed and its rôle in stored feces indicated.

The Business of Thinking

... All these things not only limit research activities in the laboratory, but effectively abbreviate and depreciate the important business of thinking. We are all familiar with the scientist who is endlessly active, but who seems to gallop all day on a ten-cent piece like a diminutive broncho plunging about endlessly and getting nowhere. Too evidently, such scientists are not indulging in the business of thinking and especially of asking questions as to the meaning of things and the planning of sound procedures to answer these questions. It should be axiomatic that the scientist must have time to think. His translatory activity in the laboratory, unsupplemented by adequate thought activity, is equivalent to

driving madly through the night across the prairie without headlights on his car and is likely to terminate in such accidents or such arrivals at or near his point of departure as find their way into scientific papers to the distress of all critical minds. Such papers seem equivalent to the "Local Items" in the country newspapers. Thinking is the searchlight which enables us to see where we are going, and to perceive such side roads as should be noted for subsequent exploration, and too obviously most of us are following established modes of research most of the time without much of what could be properly termed real thought. . . .

Preventive Aspects of Crippling Diseases*

H. E. HILLEBOE, M.D.

*Director, Division of Tuberculosis and Services for Crippled Children,
Minnesota State Board of Control, St. Paul, Minn.*

IT is particularly opportune at this time to consider the preventive aspects of crippling diseases because of the great public attention which is being focused on the crippled child. This increased interest is largely the result of the extension and improvement of services for crippled children made possible by the passage of the Social Security Act. In providing care for the crippled child, one must not lose sight of the cardinal principle of public health that prevention is the only real cure for preventable diseases as well as being the most economical and the most effective. This principle applies to the actual prevention of deformities and disabilities in the normal child as well as to the preservation of function and prevention of additional deformities in the child already crippled. It is the purpose of this paper to present some of the more recently developed methods of attack on the preventive aspects of disabling diseases in crippled children.

In order to approach a problem of this magnitude logically, it is necessary to determine the extent of crippling conditions and the variable factors involved in the order of their importance and amenability of correction. The data to be presented have been accumu-

lated over a period of years in Minnesota, whose population is approximately 2,500,000, of whom 50 per cent live in rural areas, embracing a territory of over 84,000 square miles. These factors are of importance when one considers methods of approach in a program of preventive medicine for crippled children where children must be contacted in their own rural homes.

In this state there are approximately 1,000,000 children under 21 years of age. On July 1, 1937, there were 8,300 crippled children under 21 years of age, an incidence of 8.3 per 1,000, on the central registry of the official agency. This registry does not include children with eye or ear defects alone, but includes a small proportion of non-orthopedic crippling conditions.

From an analysis of the cases under 21 years of age on the central registry, it has been determined that the causes of the disabling conditions are distributed in arbitrarily classified groups as follows: accidents, 11 per cent; anterior poliomyelitis, 20 per cent; arthritis, 2 per cent; cerebral palsies, 14 per cent; congenital deformities, 25 per cent; muscular dystrophy, 1 per cent; osteomyelitis, 4 per cent; rickets, 5 per cent; scoliosis of unspecified etiology, 1 per cent; tuberculosis of bone and joint, 3 per cent; and a miscellaneous group, 14 per cent.

On the basis of White House Conference reports of surveys, there are

* Report of Activities of Division of Services for Crippled Children to the Members of the Advisory Committee, November 1, 1937—Read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

not less than 350 blind children and 1,000 children with serious partial visual handicaps under 21 years of age in Minnesota. The same general methods of approach to the preventive aspects of other crippling diseases are also applicable to children with defective vision. In addition, there are special methods for diagnosing defective vision which must be employed. Special classes, as well as medical treatment facilities, must be provided also. The principles involved in the preventive aspects of all handicapping conditions, however, are practically the same with minor variations.

In a group of 1,274 children crippled from anterior poliomyelitis, the age of occurrence of the disease in Minnesota is as follows: under 1 year, 7 per cent; 1 to 4 years, 49 per cent; 5 to 9 years, 30 per cent; 10 to 14 years, 11 per cent; 15 to 19 years, 3 per cent. In this group of cases, the percentage distribution by age group does not differ significantly by sex. When the distribution of occurrence of disability is correlated with the age of first hospital treatment, it is found that there is quite a lapse in the age at which treatment is given in relation to the age at which disability first occurred. In 227 male children crippled by anterior poliomyelitis who were admitted to the state hospital, 71.8 per cent did not enter the hospital until 3 or more years after the occurrence of the disease; 50.6 per cent, until 4 or more years; and 38.3 per cent, until 5 or more years after the initial attack.

Bone and joint tuberculosis presents a very interesting preventive problem in this state. It is noted that less than 3 per cent of crippling conditions are due to bone and joint tuberculosis. This particular field offers untold opportunities for practising preventive medicine. The age of occurrence of 219 cases of bone and joint tuberculosis in crippled children in Minnesota

is as follows: under 1 year, 3 per cent; 1 to 4 years, 39 per cent; 5 to 9 years, 20 per cent; 10 to 14 years, 6 per cent; 15 to 19 years, 1 per cent; undetermined age under 21 years, 31 per cent.

When the first state hospital for crippled children was started in Minnesota in 1897, it was estimated that 70 per cent of the children who came to the hospital were disabled because of bone and joint tuberculosis, according to the present Chief of Staff of the State Hospital for Crippled Children. It is noteworthy at this time, 40 years later, to be able to say that less than 3 per cent of the crippling conditions found among children in the state are due to bone and joint tuberculosis, and that less than 1 per cent of the admissions to the state hospital are necessitated by bone and joint tuberculosis.

Better methods of tuberculosis control, such as improvement in the hygienic conditions, the standards of living, and the facilities for sanatorium care, have been of value in obtaining this marked decrease. One factor is probably of more importance than any other single factor—the eradication of tuberculosis among cattle. Every county in the state is accredited for tuberculosis in cattle, which means that there is less than $\frac{1}{2}$ per cent tuberculous infection in the cattle in the entire state. The type of organism usually found in the lesions of bone and joint tuberculosis in children is the bovine strain, which indicates that the original infection probably came from milk from tuberculous cows. As to this particular phase of the preventive problem of crippling diseases, the livestock sanitary group must be relied upon to assist in reducing the amount of bone and joint tuberculosis in children.

Additional factors have an important bearing on the preventive aspects of crippling conditions: (1) the age at which the disability occurs, which must

be considered in relation to the time at which treatment is first started; (2) accessibility and extent of hospital facilities and out-patient facilities for the care and medical treatment of crippled children; (3) provision for and method of follow-up of children who have been brought under the supervision of the state agency.

With due consideration of the fact that a sound educational program for the actual prevention of crippling diseases in normal children must be carried on, the official state agency has emphasized that part of the work concerned with the preservation of function and prevention of further deformities in the child already crippled, because the state agency has the facilities and field personnel necessary for the extension and improvement of this phase of the program.

The orthopedic surgeon cannot provide medical care unless patients are made available to him. It is in this part of the program that special public health tools and methods are especially effective, and must be considered an essential part of the therapeutic resources. The tools referred to are public health nursing service (including physiotherapy) and crippled children clinics in rural areas.

The field nursing service is the connecting link between the official state agency and the crippled child living in the rural community. The public health nurse discovers new cases and reopens old cases which have prematurely ceased treatment. She does follow-up work on discharged hospital patients in coöperation with the medical social worker. She carries on a preventive educational campaign in every part of her work. She prepares the local community for the proper reception of field clinics, and, in addition, makes the necessary investigations to determine which new and which old cases should come to the clinics.

She acts as a consultant to local school and county nurses in problems related to crippled children.

Whenever possible, local resources are used in obtaining information about and care for crippled children. This coöperative activity with local nursing and welfare workers is economical and avoids duplication of effort. It is imperative that numerous public health workers from different administrative agencies avoid multiple interviews of a family group for the same purpose when one worker can get the necessary information for all concerned.

Some of our public health nurses are also qualified physiotherapists. These nurses supervise the actual physiotherapeutic procedures on crippled children in their homes as recommended by the orthopedic surgeons, and, in addition, give a certain amount of physiotherapeutic treatment. This follow-up physiotherapy field service is one of the best means of preventing further deformities, particularly contractures, in crippled children who have had initial surgical treatment. The physiotherapists act as instructors and consultants to local public health nurses and are well trained to carry on an educational program for the prevention of crippling diseases.

An analysis of the records relating to the field nursing service during the past year brings out some very pertinent statistics. Public health nurses working in an area of over 84,000 square miles admitted 2,393 cases to the nursing service during that time. Of this group, 1,088 were new cases reported to the registry. In spite of the fact that at the beginning of this service there were approximately 5,000 known crippled children under 21 years of age in the state, the nurses were able to locate 1,088 additional cases in one year. This was an outstanding contribution to the program for crippled children by the field nursing service.

There was a definite shift in the age distribution toward the younger age groups in the cases found by the nursing service in comparison with the age distribution of all the known cases on the register. In addition, there was the added factor of importance in this service that, once these cases were discovered, means could be found to place these crippled children under adequate medical supervision.

In reviewing the visits made by the two physiotherapy nurses working throughout the state, it is noted that 1,257 physiotherapy visits were made. When it is remembered that physiotherapy is a very important part of the program of prevention of deformities in children already crippled, one can appreciate the value of such service even though it be difficult with a limited personnel to render this service over a large territory.

In an area in which there are public health nurses available for general public health duty, it is felt that the crippled children's division should develop a specialized physiotherapy nursing service. These nurses should have sufficient training in physiotherapy to insure that their work will be acceptable to the orthopedic surgeons in charge of the cases so that actual physiotherapy supervision and treatment recommended by the orthopedic surgeons can be given in the homes. The amount of training required to accomplish this must be determined by the orthopedic surgeons, the physiotherapists, and the schools of nursing. It is felt, however, that public health nurses who are acceptable as physiotherapists can serve in many different and important capacities not otherwise possible.

Field clinics have proved to be one of the most effective weapons in the prevention of further disability in children already crippled. The clinic is also of value as an educational means of acquainting the community, the local

physicians, and public officials with the need for a concerted program directed toward the prevention of crippling conditions in normal children. The appeal of a crippled child is universal, and when a clinic is held in a local community and people see crippled children coming to the clinic, the impression is quite lasting, and the soil is prepared for the planting and growth of a permanent educational program in the local community.

Because of the large rural territory it is possible to hold clinics in local communities only once each year. In order that every crippled child may have access to an orthopedic examination, an attempt is made to hold the clinic in the same town yearly so that it may function as a permanent out-patient department of the State Hospital for Crippled Children. These clinics are coöperative affairs, with local, county, and state groups participating.

One must take into consideration that a crippled children's clinic is quite different from a prenatal, a preschool, a tuberculosis, or a nutritional clinic, due to the highly specialized nature of orthopedics. It is possible for an orthopedic surgeon to examine a patient quickly, determine what muscles are paralyzed, what bones are in a pathological condition, and, in the majority of cases, make a definite diagnosis and recommendation for treatment. In a clinic for crippled children one is not confronted with the difficulties of determining what may be hidden in the chest of a child who is not well, or what may be found in the abdomen of a child who is complaining of vague symptoms. It is possible in these clinics to examine new cases and determine what should be done, and to follow up old cases almost as effectively as can be done in the out-patient department of a hospital. In Minnesota all of the records for crippled children

in the community in which the clinic is being held are brought to the clinic so that an accurate follow-up can be accomplished. One of the orthopedic surgeons in attendance at the field clinic is on the staff of the State Hospital for Crippled Children so that the same standard of medical care is maintained in the clinic as exists in the out-patient department of the hospital.

The functions of the clinic are multi-fold, and include all of the preventive aspects of good public health practice. By means of these clinics it is possible to reach previously unknown crippled children for an examination soon after the occurrence of their disability. Many families living 200 or 300 miles from the urban treatment centers are unable to provide transportation to bring their children to the hospital for examination. By sending the examiners out to the children in rural areas much time is saved, examinations are made at an earlier date, and definite provision can be made for hospital care if the patients are unable to provide private medical care. New cases are discovered and treatments are started soon after occurrence of disability, and as a result these patients are given medical and surgical treatment in the shortest possible period of hospitalization.

In addition to the clinic service of examination of new cases, there is the equally important work of follow-up. It is true, in most instances, that children will come to the hospitals for crippled children to receive medical and surgical care, which may require several months of hospitalization. Not infrequently, however, crippled children come to the state hospital for surgical and other corrective treatment, go home and do not return. The result is that the initial expert work is very often of small benefit due to the fact that additional treatment needed cannot be given.

A study made by the new medical

social service worker at the State Hospital for Crippled Children on 1,070 patients registered at the hospital showed that 140 patients who needed to return had been seen last 10 to 15 years previously, and that 215 additional patients who should have returned 1 to 5 years after their initial treatment had not returned at the time of the study. This means that the combined efforts of the field nursing and clinic services in coöperation with the hospital social service would be needed to prevent permanent disability and possible further deformity in 33 per cent of the 1,070 crippled children who had come to the hospital for care. Funds for any social service or field service at the state hospital were not available during the period studied.

The clinic serves as a valuable means for education of the people in the community to the need for early care of crippled children and for the prevention of crippling in normal children. The public interest aroused by the clinic, and the effect of the examinations on the parents of the crippled children and visitors, are of definite advantage in creating consciousness of the crippled children problem. In addition to the education of the lay persons in the community, the clinics have been of value to the local physicians too. Local physicians have attended every clinic which has been held, and invariably one or two physicians have stayed all day in order to observe the examination of each crippled child and to discuss orthopedic care with the orthopedic surgeon.

During the past fiscal year 12 field clinics for crippled children have been held in rural Minnesota. These clinics were strategically placed so that every crippled child wishing to go to a clinic had access to it in his own or in a neighboring county. In these clinics, 1,059 crippled children were examined. Of these, 372, or 35 per cent, were new

cases to the central registry of the State Board of Control. The majority of the new cases were referred to the clinics by field nurses. During the year the average number of crippled children admitted and examined per clinic was 88.

The age distributions of the new cases admitted to the clinics are of interest. The percentage of age distributions for those under 1 year is 4.9; 1 to 4 years, 22.8; 5 to 9 years, 24.4; 10 to 14 years, 22.8; 15 to 19 years, 23.6; 20 years, 1.6. There is a definite increase in the age group under 1 year of age in the clinic group as compared with all cases on the registry, a marked increase in the age group 1 to 4 years, and a decrease in the older age group in the new clinic cases as compared with the total group. There are many variable factors unaccounted for in this comparison, but it is strikingly evident that the clinics are bringing in for examination and treatment a large number of young children.

In 25 per cent of the total clinic cases hospitalization was recommended. When children for whom hospitalization had been recommended and approved did not come to the hospital, the field nursing staff went into the homes to investigate the cause of the delay. In addition, arrangements were made for another 28 per cent of the total number of children examined at the clinic to be taken care of in one of the out-patient departments of the hospitals for crippled children. Some of these cases were to be reexamined in future field clinics near the children's homes. When necessary, transportation from the home to the treatment center was provided by one of the local service clubs or by railroad companies. About 15 per cent of the total number of children were referred to the nursing service direct for supervision. This includes those cases which could give physiotherapy instruction

in their homes by the field physiotherapy nurses. The remaining 32 per cent of the cases either needed no special treatment or other local arrangements were made for their care.

The results already obtained by means of the field nursing service and field clinics warrant the assumption that these two public health procedures have been of definite value and will be of increasing value in the preventive aspects of the program.

It cannot be emphasized too strongly that the family physician is an integral part of any sound public health program for crippled children. He is the person who usually sees the crippled child first, and to whom the crippled child must be returned after special medical care has been given. It is possible to find out about many new patients from the local physician and at the same time stimulate his interest in the preventive aspects of crippling conditions. He may also be encouraged to make use of state facilities for the proper orthopedic care of such of his patients as are unable to provide private medical attention.

The public health nurses have done fine preventive work in bringing to the attention of the medical profession information relative to services for crippled children. In a 12 month period, 6 public health nurses working throughout this large territory have interviewed over 900 general practitioners, have acquainted them with the services for crippled children, and have emphasized the need for prevention of crippling conditions in both normal and crippled children.

The rôle played by the orthopedic surgeon in the preservation of function and prevention of further deformities is of paramount importance and is the hub of the wheel around which all complementary and supplementary services revolve. The 3 principles outlined by Orthopedic Surgeon

Hart, which are of particular value in the prevention of deformities and disabilities, are: (1) surgery when indicated; (2) fixation in optimum position; (3) physical therapy; all of which are directed toward mechanical and physiological rest of the injured or diseased part.

The orthopedic surgeon cannot carry out his principles of medical care unless patients are made available to him, preferably soon after the occurrence of the disability, and continuously once treatment has been started. It is in this part of the preventive program that public health nursing and field clinic services are particularly effective.

The combined efforts of all these forces lead to the discovery of crippled children at an early age and soon after occurrence of crippling, and result in adequate and continuous medical treatment, with a greater opportunity for complete physical rehabilitation at a minimum cost to the state.

The need for state-wide development of sight conservation and other related projects through coöperation with agencies interested in the preventive aspects of crippling diseases, is obvious. Up to the present the crippled children program in Minnesota has been limited mainly to orthopedic crippling conditions, and the statistics quoted relate to the experience in that field. However, it is to be expected that in the future various types of crippling conditions and handicaps will be grouped to include all handicapped children under one heading. It is just as important to provide care for the child who is partially seeing or hard-of-hearing as it is for the child who is crippled because of the residual effects of anterior poliomyelitis. The preventive aspects of these other handicapping conditions are fully as important as the ones briefly mentioned in this paper, and require the application of the same public health methods described above,

if permanently beneficial results for crippled and handicapped children are to be obtained.

SUMMARY

1. Actual prevention of deformities and disabilities in the normal child is a very important part of the problem of the crippled child. Emphasis by the official state agency has been placed upon the equally important part of the program concerned with the preservation of function and the prevention of additional deformities in the child already crippled.

2. The extent and distribution of crippling conditions and some of the variable factors involved in a preventive program in a state with a population of approximately 2,500,000 people, are presented.

3. The age of occurrence of various crippling diseases and conditions is presented and shows that effort must be concentrated in the early age group, during which a large proportion of the crippling occurs.

4. Three factors have an important bearing on the preventive aspects of crippling conditions:

a. The age at which the disabilities occur
b. Accessibility and extent of hospital facilities

c. Provision for follow-up examinations of children who have had initial medical care for the correction of their crippling conditions

5. Field nursing service and field clinics seem to offer an effective and successful means of reaching and maintaining supervision over the largest number of crippled children in a state with a large rural population.

6. It is emphasized that the family physician is an integral part of any sound preventive program for crippled children, and that the orthopedic surgeon is the person most competent to provide special medical care and treatment.

7. With a knowledge of the extent and distribution of crippling conditions, provision of hospital facilities for examination and treatment of crippled children, competent field nursing service and field clinics adequate enough to find children soon after the occurrence of disability, and an educational preventive program directed toward normal children, we are prepared to attack the problem of prevention of crippling diseases in its entirety and to establish a more adequate basis for the health and welfare of under-privileged and handicapped children.

The Public Health Nurse and Orthopedic Nursing Care*

DOROTHY J. CARTER, R.N.

General Director, Community Health Association, Boston, Mass.

DOES the public health nurse have a contribution to make to the care of the crippled child and the orthopedic program? If 20 years of experience in one public health nursing organization can be used as a guide, one can say with firm conviction, "Yes."

The care of the crippled child in the Boston Community Health Association was initiated by an emergency situation—the infantile paralysis epidemic of 1916. With the large number of cases suddenly thrust upon an unprepared community and the prospect of years of intensive treatment and after-care before them, the authorities turned to the agency in the city that for years had been caring for the sick in their homes. The visiting nurse knew how to enter a home, how to establish a friendly relationship with the family, how to give individual service to the patient, how to teach the family and help them to adjust to illness. What she did not have in this instance was the specific training in physical therapy needed for the follow-up treatment of poliomyelitis. This she could acquire, however, and a few nurses who had been on the staff for a number of years were given this special preparation.

They returned to the staff and initiated the program of home treatment and supervision of the infantile paralysis cases. Later a plan was worked out whereby each year one or two nurses were released to take a short intensive course in physical therapy and to return to act as orthopedic nurses in their districts. Thus a small corps of specially prepared nurses was gradually built up to serve as a nucleus for the orthopedic program.

Gradually, too, the care of other orthopedic conditions was added to the service. While we usually think of the poliomyelitis work as constituting the largest part of the program, we are always surprised on taking a census to find how many other orthopedic cases are under care. On the first day of January, 1937, for instance, we had on our records 401 active cases which were receiving orthopedic nursing treatment. Of these only 210 were poliomyelitis cases; the others included fractures, arthritis, cerebral hemorrhage, obstetrical paralysis, muscular atrophy, osteomyelitis, club foot, pronated feet, torticollis, scoliosis, etc.

Just as we have gradually added these other conditions to our case load, so, over the years, the orthopedic nurses have gradually passed on to the rest of the staff an appreciation of orthopedic nursing care. At first this was largely an unconscious process, but

* Read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

of later years has been very much a conscious one, with a definitely planned program of staff education in orthopedic conditions under the leadership of our orthopedic nursing supervisor. At present we have 10 orthopedic nurses to a staff of approximately 140 nurses, who are distributed through the various districts of the association and their activities are as follows:

1. To care for all the infantile paralysis cases in their districts.

2. To give nursing care as needed and general health supervision in those families which they are carrying for polio after-care—this may mean prenatal care to the mother, correction of defects of other children, instruction in diet, etc.

3. To carry a small district of their own for general service, similar to the other staff nurses, depending on how heavy the infantile paralysis case load is.

4. To act as consultants to the other nurses on orthopedic problems.

The general staff nurse, on the other hand, is now carrying any orthopedic case that occurs in her district with the exception of infantile paralysis. The orthopedic nursing supervisor demonstrates the treatment to the general nurse and gives her close supervision. Occasionally the general nurse has even carried an infantile paralysis case under close supervision. Thus the objective has been to make it a truly generalized program.

The orthopedic nursing supervisor directs the educational program in orthopedic care, supervises both the orthopedic nurses and the general staff nurses, and acts as a liaison between our agency and the various orthopedic clinics which refer cases to us.

Let me give you one or two examples of the cases that we have carried. Johnny Harris was only 11 months old, one of twin boys, when he was stricken with infantile paralysis, which left him completely paralyzed in both arms and legs and in the respiratory muscles. His father died suddenly of

pneumonia several months later, leaving Mrs. Harris with the two children to care for and support, one of them a helpless paralyzed baby. For 5 years our orthopedic nurse visited that home, giving intensive massage and exercise to Johnny, seeing that he was taken back to clinic periodically, watching one by one some of the more important muscles being restored, helping to keep up his mother's courage and morale as she struggled to keep the family going. Last year we were rewarded by seeing Johnny, aged 6, start at the crippled children's school, wearing braces, it is true, but with every expectation of taking his place with other children his age.

It would have been exceedingly difficult if not impossible for Mrs. Harris to take this boy to clinic regularly for treatment or to continue to give the treatment herself unaided over such a long period of time. Even in those families where the mother or father is giving intelligent and faithful treatment, we have found with 20 years of experience that the orthopedic nurse is very much needed, not so much sometimes because of the actual treatment that she gives, but because her regular visits bring encouragement and stimulation to the parents as well as to the patient, and give them the necessary impetus to carry on. I verily believe that the nurse who becomes over the years a staunch friend of the family, gives as much in hope and morale as she does in actual care and treatment.

The results that can be obtained through intensive and long-time treatment in poliomyelitis cases are so striking and well known that perhaps they do not need to be emphasized here. I do want to emphasize that the orthopedic nurse can be an important agent in giving this treatment. Not only in the follow-up care but also in the acute stage, if she can give nursing

care during that period, she can assist in preventing crippling conditions.

Less dramatic, perhaps, but just as telling is the contribution that the public health nurse can make in the care of other orthopedic conditions. There is the case of John Bailey, for instance, a husky truck driver of 35 years, who spent several months in the hospital with a badly infected hand and arm that had to be incised again and again. When he was finally discharged he was told he would never be able to use his right hand again, so badly had it become distorted and crippled. As a last resort he was referred to us for massage. The nurse worked for 3 months on the crippled arm, and again we were rewarded by seeing him return to his job with enough function to continue as a truck driver. This is an example of the kind of thing that a general staff nurse, without special training in physical therapy, can be taught to do.

Time and again when the doctor has about given up hope of restoring function in a crippled arm or leg, the nurse has kept on with the treatment and has been rewarded with partial recovery. Often, too, such recovery has meant obviating the need for an operation and other expensive treatment. Too often in the past in cases of fracture or hemiplegia in elderly or middle-aged people, have we accepted the condition as inevitable and they have become an accepted burden on the family and community. Now we are learning that often with skilled and prolonged treatment they can be partially restored as functioning individuals, and their pleasure and satisfaction therein cannot be over-estimated, let alone the saving to the family and community.

Orthopedic nursing care, important as that is, is only a part of the service that the public health nurse renders. By virtue of her preparation as a public health nurse, she can make a greater

contribution. The orthopedic patient is not *per se* any different from any other with a specific diagnosis—he is still a member of a family and of a community, and is considered as such by the public health nurse, whose service is based on the fundamental principle of the family as a unit in health teaching. Again and again we find that in addition to specific orthopedic treatment there is urgent need for guidance in matters of diet and general hygiene, not to mention in the field of mental health. Many times it is discovered, too, that the orthopedic condition cannot be relieved until some other situation has been remedied. The public health nurse because of her intimate knowledge of the family and home is in a strategic position not only to ascertain the sum total of situations which enter into the family's way of living, all of which directly affect the recovery and well-being of the patient, but also to report these to the physician in charge of the case and to assist in their adjustment, whether it be through her own services or those of another worker or agency.

There was Mrs. Lewis, for instance, 64 years old and crippled with arthritis, who was referred to us for baking and massage. On our first visit we found that she was trying to get along on what was practically a starvation diet, that she badly needed dental care, and that although she wore glasses she could see very poorly as her eyes had not been reexamined for 10 years. After many weeks and with the aid of various agencies and groups, new glasses were obtained, a set of teeth was provided, her income was supplemented to provide the necessities, and our nutrition worker aided her in working out a budget and adequate diet. While referred to us primarily for orthopedic care, it was only when these other conditions were adjusted that she began to show improvement.

Perhaps because we are fortunate enough in the Boston Community Health Association to have a nutrition service we have often found that it has helped to win the battle in many of these cases. Whether it was a 42 year old man partially paralyzed from poliomyelitis, who had to have a daily cathartic and enema until the nutritionist worked out a laxative diet for him; or the Haynes family with 4 children under 6, one of whom—3 year old Bobby—was so badly rachitic that he had to have his bowed legs broken and reset; the need for nutrition advice is of vital necessity if permanent improvement is to be expected. In fact, so imbued with the importance of adequate diet was 6 year old Johnny Harris, mentioned above, that when he was served one day with a hot dog at lunch at the crippled children's school, he refused to eat it, saying seriously that he didn't think hot dogs were very good for him! Needless to say, we do not always get such a response from our children!

If nutrition teaching is found to be an essential part of our service, equally so is the need for mental hygiene. The public health nurse, because of her association with the family over a long period of time, can give invaluable aid in helping both the patient and the family with the right approach to the patient's condition. Perhaps more effective than any direct teaching that she does in this field is the indirect value to the family of observing in visit after visit the nurse's own attitude toward the patient; her manner of talking to him; of giving understanding and encouragement without too much sympathy; of expecting him to make an effort in his own behalf and fulfil his part in making improvement, in securing an education and vocational training. I have been impressed in visiting orthopedic cases with our nurses by seeing the skill with which

they approach the patient and his individual problems, and how unconsciously, perhaps, over their years of experience they have learned to demonstrate a sane approach to the crippled individual.

While we have considered up to this time the part that the public health nurse plays in the care of the orthopedic patient, equally important is her contribution to the program of case finding and prevention. Let me cite a few examples.

One of our nurses—not an orthopedic nurse—had been giving care to a 9 year old colored girl with acute pharyngitis. On her last visit, when the girl was up and around, the nurse noticed that she walked with a slight limp. The mother was persuaded to take the child to the clinic, where she was found to have a congenital dislocation of the hip. Arrangements for an operation were made immediately and the condition which had been neglected for 9 years was taken care of.

In another instance a nurse was giving postpartum care to a mother and noticed that one of the children walked with a limp. It was found to be an old poliomyelitis case that had gone unrecognized.

An alert public school teacher was responsible for discovering another case of old poliomyelitis. It happened that she had two crippled children in her class who were under our care, and through them had learned something of the treatment. She spoke to the nurse about another boy who limped slightly, and he, too, was found to be an old poliomyelitis case and was placed under care.

The maternity service offers an unusual opportunity for preventive work as our nurses have been taught by the orthopedic supervisor, as they examine and bathe the new baby, to be especially alert to any suspicion of congenital defect, which occasionally, in the rush

of both hospital and home delivery, goes unnoticed.

To make a corps of nurses "orthopedic conscious" is neither an easy nor a quick task. It is a slow process of education and continuous "exposure" to orthopedic work and the orthopedic worker. Yet when it is accomplished, the results are so worth while and often so startling that we have never regretted the time and effort that have been put into it. We have seen new staff nurses and even supervisors who are skeptical of what can be accomplished until they work with a patient themselves, with the guidance and help of the orthopedic supervisor, and see the results. Then they are sold to it forever after.

It seems to us essential that there should be one specially trained orthopedic nurse—or for a large staff, a small corps of orthopedic nurses—to serve as a nucleus for the program. It seems to us equally essential that a conscious effort and plan be made to have that nucleus radiate through the entire staff and service. This must be done if the public health nurse is to play her most important part as an instrumental factor in the case finding and preventive program.

I do not need to emphasize how important is the relationship and tie-up of the orthopedic nurse to the other agents in the orthopedic program. The care and education of the orthopedic case of necessity involve continuous and close team work between many workers and groups, physician and clinic, physical therapy technician and public health nurse, social worker and teacher, vocational school and employer—a life cycle of coöperative endeavor and a true challenge to any community service. The public health nurse's contribution to this scheme is insignificant indeed unless she sees herself as a part of this larger program and fits in her own service accordingly. She must

know what are the potentialities and facilities for creating a useful citizen and is often the first person to turn the family's attention to a wider horizon of development and usefulness.

How shall we prepare our public health nurses for this work? By necessity we have done it in our own organization more or less, as you can see, by the fortuitous method. For those who were to serve as the nucleus of the service, the special orthopedic nurses, we have built on the foundation of their public health nursing preparation and experience and added to it intensive training in physical therapy. They have then worked on the staff under the close and continuous supervision of our orthopedic nursing supervisor. For the general staff nurse—and again I want to emphasize that her preparation for this service is fully as important as that of the special orthopedic nurse—we have again built on her public health nursing preparation, and by a planned staff educational program, the opportunity to carry orthopedic cases under supervision, and continuous exposure to orthopedic work, have gradually built up a staff of generalized nurses, not only able to carry general orthopedic cases under supervision but a staff that is "orthopedic conscious" and, we feel pretty sure, one that is making a definite contribution to the case finding and preventive program.

This is the orthopedic nursing program of one agency that already had a well established public health nursing program. How far this same program can be developed in rural areas and on a state-wide basis is another question. And yet the general principles, it seems to me, remain the same—a well prepared body of public health nurses, a group of orthopedic nurses to serve as a nucleus and act in a supervisory and consultant capacity, and a continuous staff education program. It

sounds simple, but, as many in this audience know, is far from simple in practical application. It is something that we shall have to experiment with. It has taken our organization many years to develop the program to the place where it is today, so you can see what lies ahead. There are many questions involved. Do we need more orthopedic nurses or physical therapy technicians, or both? Where does the work of one leave off and the other begin? Each has a definite contribution to make.

Again, what is the best way to prepare orthopedic nurses? I am not sure that we yet know—here, too, we shall need to experiment, and here, too, there are many questions involved. How much physical therapy does the orthopedic nurse need? Does she need to be a public health nurse-physical therapist, implying complete preparation in both fields, or is the emphasis to be on orthopedic nursing, in which her major contribution and skills are to be in her own field of public health nursing with enough preparation in physical therapy added to enable her to carry on and supervise in the home—which is her especial province—the intensive treatment that is needed. I think that if we can keep in mind the inherent contribution that each of these two groups of workers has to make—the physical therapy technician as the specialist par excellence in the hospital and in the clinic, the orthopedic nurse as the generalized health worker in the home—that it will help. And if—more important still—we can keep uppermost in our minds, the needs of the patient and the most efficient and most eco-

nomical way of meeting those needs, it will be more helpful still. What does the infantile paralysis patient, the general orthopedic case, need in the way of special treatment, general care and supervision, education? What kind of a worker, or workers, can best and least expensively meet that need? How shall this worker be prepared to give this needed service? The answers to these questions may mean that adjustments will have to be made by all groups, adjustments both in service and in preparation, but these we should be glad to make for the ultimate good of the patient.

In summing up, while there are still many questions to be answered and there is need for experimentation and further development, certain facts can be stated:

1. The experience of a number of communities, for the most part in urban centers, has demonstrated that the public health nurse has a definite contribution to make to the orthopedic program.

2. The public health nurse with special preparation in physical therapy can be an instrumental factor in the care of poliomyelitis cases, both in the acute stage and in the long period of follow-up treatment. The fact that she is a public health nurse and a family health worker makes her contribution in this respect particularly significant.

3. The public health nurse without special preparation in physical therapy can be taught to take care of general orthopedic conditions with the guidance of a special orthopedic nursing supervisor.

4. Public health nurses can be made "orthopedic conscious" through a program of staff education and continuous exposure to orthopedic work and orthopedic workers.

5. The public health nurse, because of her strategic position as a family health worker, can make her biggest contribution in the case finding and preventive program.

Social Work and the Physically Handicapped Child in the Development of a New State Program*

DOROTHY BUCKNER

Consultant, Medical Social Work, Bureau of Health, Augusta, Me.

IN the development of a new state program for services to physically handicapped children, in a state which is largely rural, and in which there previously have been no services on a state-wide basis, the problem which faces the medical social worker is that of developing effective methods for carrying out the type of medical social services which in the past have been available mainly to children in urban centers.

The methods used in setting up and carrying out an effective program will, of necessity, vary in different states because of the individual state setups, but they will essentially be somewhat similar and should be useful for comparison. It is because of this that it may be of interest to describe the preparation which was necessary before a program of services could be set up in Maine; the methods which have been used; how well they are functioning; and, at the present time, what the limitations are in the way of carrying out a complete program.

There were three vital needs which had to be met before the program could be set up. It was essential:

(1) that the medical social worker should know, correlate, and be able to utilize the resources throughout the state; (2) that there should be established a close working relation between the State Bureau of Social Welfare and the State Bureau of Health (the Extension of Child Welfare Services being in the Bureau of Social Welfare; and the Nursing Division and Services to Crippled Children coming under the Bureau of Health); (3) that the purposes of the Crippled Children's Program and the Extension of the Child Welfare Services, which are inter-related and dependent upon each other, should be carefully interpreted and understood by the community as a whole.

With these needs in mind the medical social worker, together with the Supervisor of Child Welfare Services contacted social agencies and nursing groups, both public and private, as well as the individual nurses and social workers in the field. In addition, the medical social worker spent a considerable amount of time contacting medical, social, educational, vocational, and lay organizations, service clubs, and key persons throughout the state in an effort to elicit their interest and coöperation in locating crippled children and in the program in general.

The time spent in this preliminary

* Read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

work led to a good deal of coöperation and actual participation of these groups in the program, and it acquainted the medical social worker both with the resources which were available in the state and those which were lacking and would need to be developed.

It was learned that there was a scarcity of social, educational, and recreational resources, and that it would be easier to plan for the crippled child's medical care than it would be for his educational, vocational, and social needs.

Private social agencies were found to be located mostly in urban centers and their services to be available only for clients in those centers. There were no convalescent homes, and no facilities for mental hygiene work. Although occupational therapy and physiotherapy was available in all the hospitals which would be used for treatment of crippled children, only one hospital employed a medical social worker. Teaching facilities were inadequate, in that they were available in only one hospital, where provision was made for only 10 or 15 minutes a day instruction to each child in elementary grade work. There was but one special class for crippled children in the state, and this, although held in a public school building, was supported privately. There were no provisions for teaching children in convalescent, boarding, or their own homes, except in Portland where one teacher was available for this purpose. Tuition for vocational training could be obtained for crippled children through the Rehabilitation Division of the Department of Education, but there were no funds to pay for the cost of board and room during the training period.

The Pine Tree Society for Crippled Children, a branch of the International Society for Crippled Children, had been established in the state but had never actually functioned.

It was apparent that, in a state which is 65 per cent rural, one of the difficulties in getting children to clinics and hospitals would be arranging for transportation, and that private resources for this purpose would have to be developed before clinics could be held.

Prior to the extension of child welfare services the case work of the Bureau of Social Welfare was limited to the care of Mother's Aid Families and the supervision of Neglected and Delinquent Children committed to the bureau for care and protection. Because of the limitations of the type of social services offered by the Bureau of Social Welfare to the Bureau of Health, a close relationship had not existed between the bureaus, even though both were within the Department of Health and Welfare. With the development of new Child Welfare Services, which were to be of a preventive nature, case work of the service type would be available and there would be provision for the supervision of boarding homes for crippled children.

The services of public health nurses, either employed by the state or local and private agencies, could be used throughout the state, and it would be possible to arrange for physiotherapy for patients placed in boarding homes, and in some instances in their own homes.

Clinics could be held regularly in 3 hospitals located in the largest communities and in rural areas when traveling conditions permitted. The clinics would be available to patients regardless of their financial status, the only stipulation being that the permission of the family physician must be obtained. Hospitalization for patients could be obtained at 4 private hospitals.

The determination of the patient's ability to pay in part or in full, for surgery, hospitalization, appliances, etc., could be made by the medical social worker and only those who were found

to be financially unable to pay would receive treatment free of charge. A fund for appliances, X-rays, physiotherapy, and convalescent care, would be available for use through the Bureau of Health, and a Hospital Aid Fund through the Bureau of Social Welfare for patients who had not received aid from the town or State Division of Aid and Relief within 3 months. Arrangements would have to be made with towns and the Division of Aid and Relief for the cost of treatment for patients under their care.

In order to arrange for transportation before the first clinics were held, the medical social worker met 3 area chairmen of the Pine Tree Society. These chairmen had not yet set up committees and they had no definite program plans in mind. It was agreed that active committees would be set up immediately, and that their first function would be to arrange for the transportation of children, for whom transportation facilities were not available. In addition to this, arrangements for transportation were made possible through the efforts of local service groups, whose interest and participation had been aroused mainly by the local nurses and social workers.

It was necessary to establish several working relationships in order to make it possible for medical and medical social recommendations to be carried out rapidly, and to prevent the unnecessary transportation of patients.

Arrangements were made with the Nursing Division, the Bureau of Social Welfare, nursing organizations, and social agencies, for all patients to be seen prior to coming into the clinic, by either a nurse or social worker and a refer blank filled out and sent in, together with the family doctor's consent slip giving permission for patient to attend the clinic.

The refer blanks were to supply the following type of data: Economic

Status; Religion; Medical, School and Social History; Transportation Facilities; Verification of patient's legal settlement; and determination as to whether or not the patient's family was receiving public assistance, or had received any within 3 months.

The School and Social History, in detail, was to supply the following data: *School History*: School attended (parochial or public), location of school, distance from home, transportation, age at entrance, age when leaving school, reason. Special school or tutoring, etc., High School, vocational. Time lost due to lack of transportation, time lost during hospitalization or care at home. Mental rating. School adjustment, with teacher and other pupils. Plans for rehabilitation. *Home: Physical Set-Up*, Description of neighborhood and house, number of rooms, number of bedrooms, sleeping arrangements, location of bathroom and toilet, heat and light. Suitability of home from a physical standpoint for care of patient. *Family Relationships*: Attitudes, parents to each other, parents to patient and other children, patient to parents and other children. Suitability of the home from a psychological standpoint for care of patient. *Coöperation of patient and patient's family*: Estimate of actual or potential coöperation of patient and of patient's parents regarding medical treatment. *Social Data and Comments*: Family history and background. Type of parents. Management of patient and other children. Estimate of present economic situation of family. Recreation and special aptitudes of patient, pastimes, interests, playmates, etc. Interested agencies and individuals and why interested. The key person in the social situation, whether a member of the family, a relative, a private individual, or a member of an agency.

Authorization was obtained from the Bureau of Social Welfare for the med-

ical social worker to pass on the eligibility of patients for hospital aid, and the hospitals were notified to this effect by the Bureau of Social Welfare. It was, in addition, requested of the field workers that if the patient's family had been receiving public assistance within 3 months they should obtain authorization from the local overseer of the poor, or selectmen, for the cost of therapy, appliances, or hospitalization, which might be ordered at the clinic, to be met by or through the town.

Six months after the clinics were started the Pine Tree Society was reorganized and a new president appointed. She was one of the area chairmen, who had become greatly interested in the Crippled Children's Program, and had been responsible for a local school board taking over the financial responsibility for the one special crippled children's class in the state. She was also chairman of the legislative committee for education of the Parent-Teacher's Association, and it was hoped that it would be possible, through her, to obtain legislation which would provide for the compulsory education of crippled children in their homes. The impossibility of obtaining legislation for adequate teaching facilities for children in all of the rural schools this year, however, made this impossible. A Seal Sale was conducted by the Pine Tree Society at Easter time and it is hoped that by next year there will be funds available through this society to help in carrying out plans for the teaching of crippled children in homes, and to pay for the cost of board and room for patients whose rehabilitation plans cannot otherwise be carried out. The Services for Crippled Children is directly connected with the Pine Tree Society in that the medical social worker and the Medical Director are Directors of the Society, and the latter is also a member of the Executive Committee.

For the present time the Pine Tree Society is supplying transportation in 5 areas and within the year it is hoped that the remaining areas will be developed.

I think it can safely be said that the medical treatment and follow-up of the crippled children, under the care of the crippled children's service in Maine, is being carried out adequately. Reports of clinics and hospital recommendations are being given to the nurses and social workers in the field, and they are doing splendid work in the way of seeing that these recommendations are carried out and that patients return to clinics. The clinics have consistently grown. New cases continue to increase at a steady rate and for the most part patients return when check-ups are requested. That the value of the service is realized by rural physicians is shown by the fact that more and more cases are being referred in directly by them.

The information regarding the economic status of patient's family, which has been sent in on the refer blanks, has made it possible for the medical social worker to make financial arrangements quickly for the patient's care. Arrangements for hospitalization have been made as desired by the consulting orthopedists. This is shown by the fact that, even though over 700 cases have been seen in one year, there is no real waiting list for hospitalization. Arrangements for hospitalization have been made at the time of the clinic visit and for the most part patients have been admitted to the hospital on the same day.

It has been possible for the medical social worker to make arrangements, at the time of the clinic visit, for patients to obtain X-rays, physiotherapy, and apparatus, etc.

The school, social, and environmental information which has been obtained through the refer blanks, has made it

possible for the medical social worker to interpret the social conditions of the individual patients to the orthopedic surgeon, and together with him plan for the patient's medical social treatment. This information has also served as a basis of selection for those patients and families who would need medical-social treatment.

Medical-social services have been carried out mainly by the public health nurses and by the social workers in the Bureau of Social Welfare. Where actual case work has been needed the work had been done mainly through the Bureau of Social Welfare, due to the fact that there are so few private agencies in the state. The amount of case work services which could be supplied by these workers during the past year has been limited because the plan for Child Welfare Services was in the process of development. At present the social workers in the Bureau of Social Welfare are serving as actual field staff for the medical social worker.

I think it is important to point out

that, if the development of Child Welfare Services within the Bureau of Social Welfare had not been provided along with the development of Services to Crippled Children within the Bureau of Health, it would be impossible for the latter to provide case work treatment for the patients under care.

The main limitations to the carrying out of a complete program of medical social services at the present time are: (1) the inability to arrange adequately for the education of crippled children during hospitalization and convalescence, as well as for those children who cannot attend school because of their disabilities; (2) the lack of funds to meet the cost of board and room for the children who for this reason will not be able to have vocational training; (3) the impossibility of supplying sufficient intensive medical social treatment for patients who may need help in making satisfying social adjustments. Medical-social workers are needed in the hospitals and in the field to supply skilled services before this last need can be met.

Acquired Tuberculosis in the Primate in Laboratories and Zoölogical Collections*

C. R. SCHROEDER, D.V.M.

*Veterinary Pathologist, New York Zoölogical Society,
New York, N. Y.*

TUBERCULOSIS has been a recognized major problem wherever primates have been kept for as many years as the organism *Mycobacterium tuberculosis* has been recognized in domestic animals and man.^{1, 2} The gross and histologic picture of primate tuberculous pathology in its various forms has been well described^{1, 2, 3} and compared with lesions in man both in this country and abroad. This order of mammals has not had the opportunity to build up a genetic resistance, inasmuch as the monkey does not usually encounter the disease in his native habitat.⁴ The majority feel that there is small likelihood of active tuberculosis existing in the primate in his native forest. Before a monkey could become an open case and disseminate virulent organisms, his natural enemies would have destroyed him. There is always the possibility of making contact with organisms in and adjacent to native villages while feeding on refuse. The high incidence of tuberculosis in man in and near the habitats of primates suggests a source of infection by contact after capture. Tuberculosis

mortality statistics from the League of Nations report for 1932 shows 307 deaths per 100,000 in Singapore and 613 in Manila; 294 in Panama, and 554 in Guayaquil as compared to 69 in New York and 55 for the United States as a whole. The number of primates born in captivity, which might eventually build a more resistant strain, is extremely small. Because of this lack of selective mortality, susceptibles continue to be placed in human communities where they make direct contact with frequent large doses of virulent *My. tuberculosis*, an organism to which they and succeeding generations have or will have little or no resistance.⁵

According to dealer reports, the traffic in primates is increasing. Laboratories are using greater numbers for the investigation of virus diseases; for physiological, psychological, bacteriological, anatomical studies, and experimental surgery. New zoölogical gardens, the construction of which was made possible by the Works Progress Administration, are making their appearance, some operated by city governments and others by zoölogical societies. Parks and laboratories have both made a very definite advance in the improvement of primate hygiene. The dealer on the other hand has not made

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

any marked change in his method of importing or holding primates for sale. If the animal is to be kept as a permanent exhibit and is expected to live through or exceed a normal life span, special precautions should be taken to prevent contact with large or frequent doses of *My. tuberculosis*. Usually the preventive program is weak. Shipping crate sanitation is notoriously bad. The type of construction, overcrowding, and neglect in transit is inexcusable. Paddy rice is not a satisfactory diet for a 30 day journey, and certainly not acceptable when thrown into a crate contaminated with tuberculous stools or dead specimens. Indian, Philippine, and like crews are an excellent source of virulent tubercle bacilli. Expectorating into the monkey shipping crate is almost a routine with them and the incidence of tuberculosis in this group is high. Monkeys may or may not be transferred or redistributed in new crates after receipt by the dealer. Usually the original crate continues to the monkey's destination—the laboratory, zoölogical garden, or circus. The method of shipping is as old as the business itself.

A tuberculosis-free collection must be protected from contact with new importations which may disseminate virulent organisms shortly after their arrival. Some form of diagnostic test should be used for the detection of tuberculosis and must be routinely used to eliminate those primates which may develop the disease during their period of exhibit. To understand fully the problem and to accumulate definite statistics, we prepared a questionnaire with portions acceptable to the varied groups which take part in primate traffic. It was sent to those institutions which we felt had the broadest experience. The average findings in the returned questionnaires indicate that the Bengal monkey, *Macaca mulatta*, decidedly exceeds all others in

number of importations, and is the most popular laboratory animal.

The poor response to our questionnaire, and incomplete reports, indicate that little is being done to curb the rising incidence of infection.

The incidence of primate tuberculosis including all forms is about 10 per cent annually. Of all primates that die 80 per cent are attributed to tuberculosis. One laboratory states that they can demonstrate tuberculous lesions, often latent, in every monkey destroyed over a period of years—325 specimens. The primate incidence of 10,000 per 100,000 mortality is exceedingly high as compared with the national rate of 55 per 100,000 in human beings in the United States. However, in the report by Whitney & McCaffrey,⁶ using Purified Protein Derivative in group testing in the United States, they find 47.0 per cent reactors in the all-age group, and 60.1 per cent reactors in the over 20 years group. The American Indian had the highest incidence, 72.4 per cent, the Negro second highest, 43.3 per cent.

Possibly man's allergic response is an indication of his immunity. The primate has some tissue reaction following acute infection but not enough to excite a typical allergic response of sufficient degree to be able satisfactorily and routinely to produce a tuberculous reaction. The Mantoux, Von Pirquet, Calmette, and intrapalpebral tests all give unsatisfactory results. The high susceptibility and poor or completely lacking allergic reaction in the primate suggests a relationship between immunity and allergy. Occasionally a typical reaction is seen which probably is a demonstration of temporary individual resistance. As the disease progresses dermal reaction to tuberculin diminishes. The reaction of most primates to tuberculin is similar to the reaction of man in the terminal stages of acute miliary tuberculosis.

In a group of 25 rhesus tested by me, we found 2 reactors in Mantoux and intrapalpebral tests. On the basis of experience with shipments from the same dealer, and postmortem findings, we should have had 50 per cent reactors.

Possibly a satisfactory test will be devised, which should have the following qualifications:

1. Ease of administration and interpretation (not requiring special technicians)
2. Requiring the use of a readily available tuberculin of standard manufacture
3. Requiring a minimum of animal restraint
4. Giving regular and satisfactory reactions
5. The test should be applicable to all primates so that it could become standard.

Complement-fixation has been suggested, but the routine collection of a satisfactory serum sample from all primates would be extremely hazardous. The Mantoux test is difficult to apply because of extremely thin vascular skin. We have found the belly the best field to be shaved. Here skin can be picked up between thumb and finger and with care an intradermal injection can be made using a 28 gauge needle. The point of injection can be outlined with mercurochrome. The reaction, should it occur, can be definitely measured. The Von Pirquet test can be applied at the same site, using two types of tuberculin and plain broth. The scarified areas here also may be marked with mercurochrome and numbered. The intrapalpebral test is easily given, using the 1 c.c. tuberculin syringe and 28 gauge needle. The monkey is held on his back, arms behind him, legs extended. The lower eyelid is picked up with the needle point bevel up, the needle inserted and tuberculin injected to leave a lentil-sized raised area. The Calmette ophthalmic test is of course the most simple to give, and some report satisfactory results.⁷ We have not had

routinely satisfactory reactions with any of the described tests. We have used bovine type K.O.T. (synthetic media), 0.25 gm. per c.c.; human type tuberculin K.O.T., and also the dilution "C," 0.1 mg. per 0.1 c.c.; human tubercle bacillus protein MA-100, 0.01 mg. of protein per 1.0 c.c.; and Purified Protein Derivative (P.P.D.), using the human first strength dose of 0.1 c.c. containing 0.00002 mg. P.P.D.; and 0.1 c.c. containing 0.005 mg. P.P.D. second strength; and also double strength using 0.01 mg.⁶ Even the concentrated tuberculins failed to produce a reaction in known tuberculous monkeys. The subcutaneous test depending on a systemic thermal response, applied to primates by Penrose, White, Brown, and Pearson of the Philadelphia Zoological Society,⁸ is successfully used in the hands of Fox and Ratcliffe of the⁹ same institution. The objection to it lies primarily in the long continued restraint necessary to establish the peak 3 P.M. rectal temperature and subsequent temperature reactions following the subcutaneous administration of tuberculin. The weight curve represents an important diagnostic criterion in all acute forms but it loses its value in the young growing monkey. Roentgenographs have real value but involve too great expense for routine tests. Some laboratories rely almost entirely on the relationship of weight curve to chest picture for a diagnosis. Probably 80 per cent of *My. tuberculosis* infection in primates is acquired between the time of capture and eventual delivery. A program of control which would aim first at importations should be instituted with federal control. Such a measure, however, would be entirely impractical until a satisfactory diagnostic test is devised. Sputum, if it can be secured, and stool concentrations are interesting sources of tubercle bacilli but routine dependence on these is not practical. Some primatologists

feel that they can identify the tuberculous animal by its appearance. In the course of its investigations a tropical laboratory destroyed 539 monkeys at large in the forest and never demonstrated a tuberculous lesion; however, the species investigated has a high incidence in its own captive group.

The order Primates should be an ideal source of study of tuberculosis from the epidemiologist's point of view. Contacts can usually be traced. It does not usually develop active immunity and presumably it comes from a tuberculosis-free community. The disease is usually epidemic during shipment and early handling and only becomes endemic where control measures are in force. The Philadelphia Zoological Society has proved that it is possible to maintain a tuberculosis-free collection where the disease had peak 20 years ago. It is understood that to establish tuberculosis in the primate as in man, large or repeat doses of virulent organisms are necessary to bring about an active infection, but when the disease becomes established in the primate its prospect of developing a passive congestion with resulting fibrosis and calcification is quite remote. If it had no resistance at all we might expect 100 per cent mortality, for certainly every primate in captivity has ample opportunity to contact small doses of *My. tuberculosis*. Old World monkeys are most susceptible; however, acute epidemics are possible in New World species. A tropical research institution experienced a tuberculous epidemic in its Spider monkey (*Ateles ater*) colony. All were destroyed and the colony reestablished. The contact here was a known open case in the human attendant. There is apparently a zoölogical family and genus variation to resistance; however, the degree of susceptibility and sub-

sequent active infection is dependent on the extent and degree of contact.

Unfortunately, all primates do not have a postmortem examination. The group that do are usually those valuable specimens in zoölogical gardens or the experimental monkeys in the laboratory that require an accurate postmortem report to complete the experiment. Some laboratories make a detailed report but seldom include a case history. A number fortunately do conduct a satisfactory examination and give pointed information, usually of a comparative nature, which should lend further impetus to the epidemiological investigation of human tuberculosis.

Deaths in young monkeys are usually found to be the acute miliary form and generalized, with outstanding pulmonary lesions. The older primate may have more extensive lesions with pulmonary caseation and cavitation, and caseous lesions in spleen, lymph nodes, and liver. We do not often see meningitis or bone involvement and serositis. Pott's disease is occasionally seen and recently we demonstrated a tuberculous serositis in a *Hamadryas* baboon (*Papio hamadryas*). Another of the same species had an acute tuberculous meningitis. A performing chimpanzee, 5 years old, had a tuberculous meningitis with cerebellar infiltration. Tuberculous pneumonias are common, especially in the anthropoid apes. It is decidedly uncommon to have fibrosis with calcification. Scrofula is occasionally seen. In all probability the older primate has developed some resistance and consequently the organism produces larger and more extensive lesions than in the young. Routinely, sections should be cut from suspected tissue, especially lung. Much gross atypical tissue proves to be tuberculous. Most laboratories routinely make a gross observation and attempt to demonstrate acid fast organisms.

Where guinea pigs have been injected and tissue concentrates cultured, the human type of bacillus has usually been found.

To assure a good source of tuberculosis-free primates for zoölogical gardens and laboratories, we recommend that the local dealer be advised of the necessity of improving the primate hygiene immediately after capture. The monkey must avoid contact with human open cases and be held in smaller groups than is the custom (maximum: 10 in a cage). Where possible the shipping crates and holding cages should have some form of open mesh floor to prevent contact with tuberculous stools. A satisfactory disinfectant should be used routinely. All sick and suspected open cases of tuberculosis are to be isolated or destroyed. The use of a diagnostic test is not recommended at this stage, inasmuch as the most reliable subcutaneous test, with thermal reactions, could not be conducted practically.

The experienced animal dealer and keeper recognizes a sick monkey—if not tuberculosis—and it is our belief that those monkeys which are disseminating organisms will demonstrate either respiratory symptoms, draining scrofula, or diarrhea. These monkeys should be destroyed or isolated. It is most difficult on shipboard to remove one or more dead or sick specimens from a small crate, 2 by 3 feet, with 30 to 50 young *M. mulatta* active and alert awaiting an opportunity to leap out. Monkeys enjoy and need their mutual warmth but they will have a greater survival rate if they are given more room. The shock of capture, crating, holding, and eventual shipping to a new life zone can most satisfactorily be cared for by giving best possible food with the necessary vitamin supplements. The time consumed in transport should not be considered as part of quarantine because it is not a

tuberculous quarantine at all, but a period of likely exposure. When the shipment arrives at the port of destination a further physical stress is experienced in the transfer from ship to dealer's quarters or to train for final destination.

Holding quarters in metropolitan areas are poor. There is a general lack of sanitation. The lack of satisfactory disinfection is often due to improper claims by the manufacturer or his representative. The efficiency of their product is usually determined by its ability to replace an obnoxious odor with a pleasant one. The standard 4 per cent solution of liquor cresolis comp. U.S.P. used hot makes an efficient cleanser and disinfectant. Coal tar derivatives are well tolerated by primates. Often an odorless disinfectant is desired and according to the U. S. Department of Agriculture, *Circular Letter 1750*, B.T.B. (Sodium orthophenolphenate) used in a hot aqueous solution, 2 per cent by weight, is quite satisfactory for the specific destruction of *My. tuberculosis*. If unpainted stainless steel or galvanized metal is used in cage construction, lye 1:200 is quite satisfactory. Concrete makes cheap permanent construction but is too damp, cold and uncomfortable for monkeys. Paraffin-saturated wood, rubber compositions, cork block, or especially compounded materials are used with success. The most satisfactory floor from a sanitary standpoint is the electric weld 12-14 gauge wire with $\frac{3}{4}$ " squares for small monkeys, $1\frac{1}{4}$ "- $1\frac{1}{2}$ " for larger animals. In permanent buildings structural glass or smooth finished plaster walls and ceiling are recommended. Sheet metal is best for the temporary or portable cage. It is also important to avoid contact between the primate and the visitor in the zoo. The most effective method is to erect a full glass partition between them. This method prevents the pas-

sage of various upper respiratory infections to the monkey from man, in addition to preventing the carriage of pathogens on food from visitor to exhibit.

We can approximate the number of primates sold annually from the estimated and actual sales figures of the Eastern dealers: *Macacus* sp. 25,000 (*rhesus* and sp.); anthropoids 250; all others 10,000. The incidence of tuberculosis is likewise a relative figure, probably exceeding 50 per cent, including latent forms, and 5 per cent open cases. There are major inaccuracies in our submitted figures. We know that the majority of *M. mulatta* originate from the same dealers, and we do not believe it possible to have 95 per cent tuberculosis infection with approximately 30 per cent acute phthisis in one group and a negative report from another—all monkeys originating from the same dealer. The incidence of tuberculosis is apparently directly proportional to the accessibility of a competent pathologist. We do not propose to state that all primates die as a result of *My. tuberculosis* infection. Trauma with or without septicemia, common cold, and bacillary dysentery cause many deaths.

Let us critically review the experience of typical buyers. A zoological society received 200 *M. mulatta* to populate a monkey island. Ten days after receipt they experienced 10 per cent mortality. During the course of the summer 125 monkeys died. All deaths were attributed to acute tuberculosis on pathological diagnosis by a competent pathologist. A physician who purchased 40 *M. mulatta* for experimental surgery had a 50 per cent loss attributed to tuberculosis before his experiment was complete. A city laboratory lost 30 per cent of a group during the course of titrating poliomyelitis pooled sera. A state institution found 98 per cent tuberculous

lesions in all *M. mulatta* that died or were destroyed, with a major incidence of active infection. The dealer is, usually, not knowingly, a party to the sale of animals with infectious disease. He is sincere in his belief that he is selling a normal specimen.

The zoological garden's aim is longevity. Consequently because of a long quarantine, attempted early tuberculosis diagnosis, a definite sanitary program, and best possible nutrition, it usually has a lower incidence of infection than the experimental laboratory.

SUMMARY

Primate tuberculosis and its pathological forms have been a major problem as long as *My. tuberculosis* has been recognized. It has become both an economic and public health problem. Its incidence has not decreased, because of lack of genetic resistance and poor hygiene. The 10,000 per 100,000 mortality rate is 200 times that of man. The human type of organism is usually demonstrated. There is family and genus resistance variability but no measured resistance within a species. Antemortem recognition of the disease in the order of popular application consists in

1. Physical examination
2. Weight curve
3. Subcutaneous tuberculin test with thermal reaction. Mantoux and related tests are not routinely successful. (The primate has an indifferent allergic response to tuberculin.)
4. Roentgenography (usually in combination with weight curve)

Postmortem diagnosis consists routinely in demonstrating an acid fast organism (usually primary Ziehl-Neelson stained smear, occasionally animal inoculation or culture with subsequent smear) from typical lesions (histopathological if gross lesion is atypical). Better shipping hygiene with improved final housing and avoidance of contact with open cases

in primate or man, are most important if the incidence of acquired primate tuberculosis is to be lowered.

American Verbosity

THE responsibility for American verbosity, I feel sure, lies with the very efficient American stenographer, and the temptation to garrulousness provided by the skill of her fingers. In some offices it seems that letter-writing has become a major undertaking, like writing for publication, and not a means to an end. There is no one who appears to be quite so well satisfied with the result of a day's work as the American business man who has dictated so many letters that his secretary has to work overtime transcribing them. The first practical evidence I had of the existence of the depression in America came when I noticed that the letters I received were fewer and shorter. Obviously, it had been necessary to reduce the staff of stenographers. Business must be improving now, the letters are growing in fre-

quency and length and will soon be what they were in 1928.

It is my candid opinion, after reading these letters for about 20 years, that half the typewriters in America could be scrapped and half the stenographers married off, and the wheels of business would run just as fast and with a good deal less noise and waste effort. Businesses in other countries are conducted successfully with only a fraction of the amount of correspondence Americans appear to find necessary. Every man whose business it is to dictate letters should be compelled to read over, at the beginning of every business day, the copies of the letters he dictated one year before and see for himself how many of them were twice as long as necessary, and how many were not necessary at all.—Carl Crow—Harpers', June, 1937.

Industrial Hygiene Applied to the Clothing Manufacturing Industry

WILMER H. SCHULZE, PHAR.D.

Director, Bureau of Environmental Hygiene, City Health Department, Baltimore, Md.

THE development of an industrial hygiene program in the Baltimore City Health Department was contemplated in 1931 and an opportunity to inaugurate actual field studies was presented during 1932 when the department was called upon to investigate alleged insanitary working conditions in some of the clothing manufacturing establishments in Baltimore. The Commissioner of Labor and Statistics of Maryland furnished a list of establishments in which the working environment might be found to be unfavorable. Inspections were made of this group of 206 plants, attention being given first to such items as were considered of most health significance, such as carbon monoxide hazards, the use of the common drinking cup and the common towel, and secondly to sanitation, lighting, and ventilation. Conditions found in many of the plants demonstrated the need for a study of the working environment in all establishments engaged in the manufacture of clothing.

In 1933, 3 inspectors of industrial hygiene were appointed in the Health Department. After a brief course of training in industrial hygiene they were assigned the task of making a survey of all clothing manufactories in the city. A survey card was designed to be used by the inspectors and included information pertaining to accident and health hazards, sanitary facilities, general sanitation, lighting,

and ventilation. The data from the cards were tabulated; and the percentage of establishments showing the different types of unsatisfactory working conditions are shown in the table. Comparison of these figures with those for 1932 indicated that carbon monoxide hazards were quite prevalent throughout the industry while insanitary working conditions were confined to a relatively smaller percentage of the plants.

Under a state law all clothing manufacturers are required to obtain a permit for operation from the State Commissioner of Labor and Statistics. It was agreed that these licenses be issued annually and would not be renewable unless the manufacturer coöperated with the Health Department by correcting unsatisfactory working conditions. To obtain improvements and to eliminate health hazards letters were written the managements of plants outlining the conditions which needed correction, explaining their relation to the health and welfare of their employees. These letters were followed up by visits to the plants, at which time further explanations of the contents of the letters were given and the interest and coöperation of the plant officials were solicited.

A second complete survey of the industry was made in 1934 to ascertain the effectiveness of the educational procedure carried on to obtain improve-

ments in working conditions. The results are given in the table and show a marked improvement in most of the conditions tabulated and demonstrate the value of educational efforts in an industrial hygiene program.

To determine the effectiveness of the program another complete survey was conducted during the winter months of 1936-1937. The results are also given in the table. While they show some improvement over the 1934 survey they indicate that attention need be concentrated on only a relatively few plants instead of a large percentage of the establishments.

The clothing manufacturing industry in Baltimore is composed of over 400 establishments employing from 2 to more than 100 employees. Of the 428 establishments inspected in the 1936-1937 survey 44 per cent employed 10 or less workers while 33 per cent employed between 10 and 50. Only 10

per cent of the plants employed more than 100 persons. With the industrial improvement during the last few years there has been a tendency toward moving into larger and more suitable quarters, with attending improvement in the general working environment.

Because of the prevalence of potential carbon monoxide hazards in the clothing manufacturing industry in connection with the use of gas fired hand irons for pressing and gas fired boilers considerable study was given these appliances. Actual determinations of the concentrations of carbon monoxide at breathing levels with the carbon monoxide indicator were carried out in a number of instances during all the surveys and in some cases concentrations above the physiological limit were found. These were generally due to leaky gas tubing, deterioration of appliances and defective venting of gas fired equipment. After corrections

TABLE I
*Surveys of the Clothing Manufacturing Industry**

	1932	1933	1934	1936-1937
<i>Number of establishments</i>	206	462	445	428

* Percentages refer to establishments

† Sight Meter readings on work-plane

were made subsequent tests were carried out to insure elimination of the carbon monoxide hazard.

SUMMARY

A study of working conditions made during 1932 in a representative number of clothing manufacturing establishments revealed the existence of health hazards in addition to insanitary con-

ditions in a significant percentage of the plants. By applying educational efforts in the form of reports to and conferences with responsible plant officials marked improvements in the working environment were attained. The results of this application of industrial hygiene services to the clothing manufacturing industry over a period of several years are shown in the table.

Nutrition

IN routine examinations, physicians differ widely in their estimates of the nutritional status of the same children.

The differences in judgments are so great that estimates based on a single examination are of little value in determining the relative amount of malnutrition among any group of children at any one time or changes in the amount from one time to another. Neither are these nutritional estimates reliable bases for determining which children of a group are malnourished.

It is therefore suggested that prac-

tical nutritional programs be focused on correcting the faulty food habits of children rather than expending energy on routine examinations to determine nutritional status. It is also proposed that research workers concentrate on the construction of valid methods of determining nutritional status rather than making surveys which are of doubtful significance because of the inaccuracies of the estimates upon which their findings are based.—Reliability of Medical Judgments on Malnutrition, by Mayhew Derryberry, *Pub. Health Rep.*, Vol. 53, No. 7, February 18, 1938.

Necropsy Evidences on the Relation of Smoky Atmosphere to Pneumonia*

SAMUEL R. HAYTHORN, M.D., AND HARRY B. MELLER

Director of the William H. Singer Memorial Research Laboratory of the Allegheny General Hospital; Head of Air Pollution Investigation, Mellon Institute and Chief of the Bureau of Smoke Control, Pittsburgh Department of Health, Pittsburgh, Pa.

THIS report represents another step in the program of studies made over a number of years by an interested Pittsburgh group in an effort to find the relation which they feel exists between the local smoky atmosphere and the high death rate from pneumonia. Most of the more recent studies on the effects of dust have dealt with various forms of industrial pneumoconiosis. Clinical investigations of employees, group surveys, and roentgenologic examinations of large numbers of workers engaged in like occupations and supplemented by animal experimentation have united to advance our knowledge of the importance of air pollution on the health of industrial workers, but the fact that there are milder changes in the respiratory systems of persons living in smoky and dusty atmospheres which appear to influence health has received only casual attention.

Pittsburgh presents an unusual opportunity for the study of the relation of smoke to pneumonia for two reasons: The annual death rate from pneumonia is higher than that for the State of Pennsylvania, and the atmosphere is laden with dust and smoke, particularly during the fall and winter months when

the rate is highest. Several efforts have been made to show whether the relation is that of cause and effect or merely coincidence, and it is our present purpose to review the evidence accumulated and to add to it the data acquired through the analysis of the findings in the lungs of 3,000 persons dying from various diseases in Pittsburgh hospitals. The examinations were made for the purpose of determining the kinds and extent of lung changes and the amount of visible dust deposits. It should be emphasized that this series of cases does not comprise an industrial group but represents a cross-section of the general inhabitants, including women and children as well as representatives of the professions and those of dusty and non-dusty trades. After the first series, children under 10 years of age were omitted.

The first comprehensive study of Pittsburgh's smoke problem was conducted by the Mellon Institute of Industrial Research in 1911-1913.¹ In commenting on certain medical phases of the problem, White² called attention to the fact that the "smokiest" wards had the highest death rates from pneumonia. This observation was substantiated in sootfall studies made in 1923-1924 and 1929-1930 by one of us (Meller).³ The statement could not be accepted as final until other environmental factors were in-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

vestigated for the reason that sections having the highest sootfall were in the valleys, along the rivers and railroads and in the vicinity of industrial plants where economic conditions and occupational factors sometimes complicated the picture. Moreover, sootfall alone cannot be taken as a perfect indicator of respiratory damage, since it includes those particles that fall by gravity or are brought down by rain, whereas it is only the very small particles (10 microns or under) that are retained in the lungs.

A second observation¹⁰ made during the early investigations was to the effect that a higher per cent of pneumonias than had been reported elsewhere failed to resolve in the usual way by crisis and healed by organization of the exudate in a way similar to the process of healing of an incised wound. It was suggested that this type of healing resulted from imperfect drainage of groups of air sacs due to the closure of lymphatic channels by dust deposits.

In addition to the sootfall studies mentioned, it has been noted from time to time that following periods of several days of continuous smog (mixtures of smoke and fog) the number of deaths from pneumonia is increased. This observation could easily be evaluated if incidence rates of a dependable character, rather than death rates, were available.

It is obvious, when suspended solids are considered, that the concentration at a given time depends largely upon three factors: volume of pollution admitted to the atmosphere, especially during the winter or heating season; the temperature, which controls to a large extent the amount of fuel used for heating purposes; and the velocity of the wind necessary to carry the smoke away. Observations with the Owens's automatic filter in use in Pittsburgh show that there is a high

degree of correlation among these factors in the production of smog.

The data on weather conditions and the daily death rates from pneumonia have been kept for several years, and tables placing these facts side by side have been compiled. One difficulty has been to get a basis for analysis that can be depended upon. The first problem was to calculate the amount of time that must elapse between a smog period and the time at which its effects, if any, would be reflected by the pneumonia death rate. Meakins⁴ states that where the incubation period of pneumonia is known, it is usually from 36 to 48 hours and that while resolution by crisis may occur any time from the 3rd to the 14th day, it rarely occurs before the 5th, and is more likely between the 5th and 9th days. Death may occur at any time, but generally is related to the critical period. With full appreciation that this period may vary more or less either way, we allowed 2 days for the incubation period and 6 to 8 days for the termination of the disease, and assumed that the period of 8 to 10 days would be the probable time for the rise in the death rate to appear.

Actually, periods of smog, during the winter months, are commonly followed after several days by periods during which an increased pneumonia death rate occurs. While these examples do not appear with sufficient regularity to be conclusive and do not always fall at the times they are expected, they are frequent enough to be suggestive. The following tabulations are examples of the relation of wind velocity, temperature, and smog to the death rate of pneumonia (see Tables I, II and Graph I).

VARIATION IN PNEUMOCOCCUS TYPES IN PITTSBURGH

Another angle to the problem has been the persistence for at least 15

years of more than 50 per cent of pneumococcus types in groups higher than the fixed Types I, II, and III. McMeans, 1918-1926,⁵ and Robinson, 1925-1935⁶⁻⁷ reported on typings made routinely on all pneumonia cases admitted to hospitals. Many of the strains less commonly recorded in reports from eastern cities have been found to be rather common and very virulent here. During the highly fatal epidemic of 1936-1937, the collected reports of typings from 7 Pittsburgh hospitals showed 65 per cent that fell in the group formerly classed as Rockefeller Type IV.

PITTSBURGH'S PNEUMONIA MORTALITY RATE

In the foregoing discussions several references have been made to the high pneumonia death rate. A review of the

annual rates for males, females, and totals for the last 10 years is submitted in support of the statements (see Table III).

Prior to 1927 the rate was commonly more than 200 per 100,000 inhabitants, and in 1923 an all-time peak of 374.4 was reached. In comparing the city rate with that of Pennsylvania State, the Pittsburgh rate is often as much as 40 per cent higher. For 1935 the city rate was 140.5; the Allegheny County rate was 121.9; and the state rate was 83.5 per 100,000.

Meakins gives the death rate for women as generally higher than men and the ratio as about 27 to 20. The rates for males and females were computed separately in the hope that the influence of industrial factors would be brought out. The number of males exceeded the females each year for the

TABLE III
Ten Year Mortality Rate for City of
Pittsburgh

Year	Males Per 100,000	Females Per 100,000	Total Per 100,000
1927	197.1	122.3	159.6
1928	238.1	186.5	212.6
1929	226.1	127.9	176.7
1930	224.3	125.7	174.7
1931	287.8	131.1	208.8
1932	166.5	126.1	146.1
1933	107.1	76.8	91.8
1934	169.8	99.6	134.5
1935	168.5	112.9	140.5
1936	210.1	125.2	167.4

time studied. The factors leading to the reversal of sex occurrence were not apparent.

It is further seen in the chart that during the years from 1932 to 1935 when the depression was at its height, when air pollution from industrial flues was greatly decreased and when economic and living conditions were at their worst, there was a great decrease in the number of deaths from pneumonia. However, the decrease occurred in females as well as males so that the change cannot be attributed to conditions within the plants, such as overheating and rapid chilling of the employees.

NECROPSY STUDIES

The accumulated facts brought out in the above review led to a search of the postmortem records of several large hospitals for additional data that might bear on the pneumonia problem.

As the first step, the lungs, removed at autopsy from 3,000 persons dying from any cause in our general hospitals, were graded microscopically for the amount of extraneous pigment and the resulting fibrosis. Later, the presence of "all forms" of pneumonia including bronchopneumonia, lobar pneumonia, hypostatic pneumonia and organizing pneumonia was recorded by grade. The analyses and gradings were made in 3 series. In 1933 Schnürer, Allison, Boucek, and Hay-

thorn⁸ published a preliminary report on the analysis of 2,499 postmortem examinations graded for "anthracosis" * on the following criteria:

Grade I. Carbon pigment phagocytes in alveoli. Few in perivascular lymphatics.

Grade II. Wide distribution of phagocytes—in all portions not averaging more than three rows of cells.

Grade III. Widespread distribution of phagocytes of three or more rows of cells. Moderate compression of cells by fibrous tissue.

Grade IV. Extensive distribution of phagocytes with fibrosis in peribronchial, perivascular and subpleural lymphatics.

Grade V. Excessive fibrosis and pigmentation—puckering of pleura—perivascular—peribronchial—and intra-alveolar accumulations of phagocytes.

The first report included consecutive autopsies from several large hospitals in the City of Pittsburgh† covering a period from 1912 to 1935.

The second series was made by Schnürer⁹ who reviewed 342 cases at the City Home and Hospital at Mayview, about 8 miles from the city, and the tuberculosis camp of that institution.

A third series was graded by Haythorn on cases over 12 years of age during 1934–1935 in order to bring the total number of cases up to 3,000.

Table IV shows the separate gradings for each series and the total results for the 3,000 cases. The results were fairly consistent in each series. Series 1 and 3 were made up of general hospital cases and included the records of persons of all ages and walks of life. The second series was a limited group of indigents whose average age fell within the period of life at which pneumonia is most common.

* While the series contained examples of other forms of pneumoconiosis, such as bituminosis and anthracosilicosis, the term anthracosis is used as the best known and at the same time the one least used in reporting industrial diseases.

† Allegheny General Hospital, Mercy Hospital and Pathological Department of the University of Pittsburgh.

TABLE IV

	Series 1	%	Series 2	%	Series 3	%	Total	%
Pigment Free	179	7.16	0	0.0	0	0.0	179	5.95
Grade I	289	11.56	30	8.77	20	12.57	339	11.30
Grade II	767	30.69	112	32.74	44	27.67	923	30.76
Grade III	778	31.11	146	42.69	45	28.30	969	32.30
Grade IV	354	14.14	46	13.45	40	25.15	440	14.66
Grade V	132	5.03	8	2.33	10	6.28	150	5.00
	2,499	99.69	342	99.98	159	99.97	3,000	99.98

The age factor is very important with reference to pneumonia incidence, and the average ages for the various grades were found to be: Grade 0, under 10 years; Grade I, 10 to 15 years; Grade II, 35 to 40 years; Grade III, 50 to 55 years; Grade IV, 55 to 60 years; and Grade V, back to between 50 and 55 years.

For comparison, the sex incidence had to be reduced to per cent rather than cases, since considerably more men than women were examined. The percentage sex-incidence was about equal for Grades I, II, and III, largely male for Grade IV, and almost entirely male for Grade V (see Chart 1).

Based on sex and age incidence, Grade IV was a mixed occupational and non-occupational group, while Grade V was definitely occupational and included 41 cases that had given their occupations as coal miners.

CHART 1

■ = Grades of Anthracosis

There was some unavoidable overlapping in Grades IV and V so that too sharp conclusions could not be drawn in separating them.

VARIETIES OF PNEUMONIA INCLUDED

It is not always possible to differentiate the various forms of pneumonia, either clinically or by microscopic examination. In contrast, lobar pneumonia is a definite clinical and pathological entity. Therefore, in Chart 2, the occurrence of pneumonia is classified as "all forms" including bronchopneumonia, lobar pneumonia, septic pneumonia, hypostatic pneumonia, and organized pneumonia. Lobar pneumonia was then tabulated separately in another column. Organization was accepted when areas of healing with the formation of new vessels and proliferating fibrous elements were present in the alveolar exudates but was excluded when found to be associated with infarction, gangrene, chronic empyema or tuberculosis.

Separate tables were prepared to show the pneumonia incidence by grades for each of the 3 series, but the differences found were slight and do not justify their inclusion in the report. Only the composite totals are shown in Chart 2.

While pneumonia in some form was present in 47 per cent of the cases, it must not be forgotten that the entire group was made up of hospitalized, sick patients and that many of the pneumonias were terminal infections rather than primary diseases.

In trying to answer the question as

CHART 2

- = All Forms of Pneumonia
 ▨ = Lobar Pneumonia
 ■ = Organizing Pneumonia

to whether anthracotic deposits in the lungs predispose to pneumonia or tend to make it more fatal, we compared the lesions with the relative mortality as it was found in the several anthracotic grades.

The per cent of pneumonia "all forms" was quite constant in Grades 0, I, and II and ranged from 40.7 per cent to 45.8 per cent. The average age of each of these grades was under 40 years, before which time pneumonia is generally less fatal than in later years. In contrast, the average ages for each of Grades III, IV, and V fell between 50 and 60. Yet, the rate was 49.9 per cent in Grade III, 54.3 per cent in Grade IV, and 52 per cent in Grade V, suggesting that factors other than age were needed to explain the differences in per cent between the latter 3 grades.

Theoretically, lobar pneumonia should have been a better index than "all forms" since it is less frequently a terminal infection. Here again, definite conclusions could not be drawn because the age factor could not be evaluated. Grouping Grades 0, I, and II, there were 1,441 individuals in-

cluded and only 168 of the 499 cases of lobar pneumonia found in the 3,000 records studied. Since it is well known that pneumonia in children and young persons almost always heals by crisis, the fact that the lymphatics had not been seriously damaged in these earlier groups may have been a factor.

Beginning with Grade III, the pneumonia age was entered, and the lobar pneumonia incidence rose from 12.9 per cent to 21.6 per cent. In Grade IV it remained constant at 21.8 per cent, and in Grade V it receded to 17.3 per cent. The decrease may have been apparent, due to the fact that Grade V included only 150 persons and was too small for conclusions.

When organizing pneumonia was studied, significant facts began to appear. When Grades 0, I, and II are combined, the number of instances in which organization was found to be present was only 2.63 per cent. When Grade III was examined, not only was it found that the pneumonia incidence had increased, but there was a very appreciable amount of blockage of the lymphatics and an accompanying rise in the incidence of organization to 7.2 per cent. In Grade IV the lymphatic blockage was progressively greater, and the organization incidence again increased to 9.1 per cent. By the time Grade V was reached, there could be no doubt about increased incidence of organization, since it reached 16.7 per cent, and all of the 3 series of gradings, made separately, showed comparable advances.

Grade V appeared to be an industrial group. The lungs showed heavy, black pigment deposits in the subpleural, peribronchial, and perivascular lymphatics with definite microscopic, fibrous tissue changes and small emphysematous pockets in the air sacs about the fibrous thickenings. Of the 150 cases in this group, 25 presented

greater or lesser areas of exudate undergoing healing by organization.

Two of many things may have contributed to the organization: The closed lymphatics may have made healing by crisis difficult by decreasing the facilities for drainage and the small areas of emphysema may have been foci of relative inactivity during the respiratory expansions of the lung tissues. While it has not been shown that the expansile action has anything to do with the rapid resolution of the pneumonic exudate, it is likely that it does.

There were a few instances of anthraco-silicosis in Grades IV and V, but these did not seem to show any greater amounts of organization than did the lungs with the black, almost non-crystalline pigment deposits.

There could be no doubt that organizing pneumonia was more prevalent in the high grades of anthracosis, although the evidence as to whether the relation is that of cause and effect was not proved.

CONCLUSIONS

1. The protocols and microscopic sections of 3,000 necropsies were reviewed, the cases separated into pigment-free lungs and 5 grades of anthracosis depending upon the amounts of extraneous pigment and the fibrosis present. Grades 0, I, and II appeared to have no particular occupational basis. Grade III was a mixed non-occupational and occupational group. Grades IV and V were largely, although not exclusively, occupational.

2. The incidence of pneumonia "all forms" and of lobar pneumonia was tabulated in relation to each grade of anthracosis. In spite of the high local pneumonia death rate, no anatomical evidences of a relation between the incidence of pneumonia and the milder

grades of anthracosis in the non-occupational groups could be demonstrated.

3. In Grades III, IV, and V there was a definitely higher percentage of pneumonia cases, but the average age for each of these grades coincided with the period of life at which the pneumonia death rate in less smoky communities is likewise highest.

4. Healing by organization of unresolved pneumonia was consistently higher in all of the more advanced grades of anthracosis and greatest in Grade V. The organizing foci appeared to be associated with heavy pigment deposits, microscopic areas of fibrosis, and isolated emphysematous pockets in fibrosed portions of the lungs.

5. Nothing tangible was found to connect the pigment deposits with the high pneumonia incidence and high mortality rates, but the association of severe anthracosis and healing by organization formerly reported was verified.

Physique and Health

JESSE FEIRING WILLIAMS, M.D., F.A.P.H.A.

Professor of Physical Education, Teachers College, Columbia University, New York, N. Y.

THE thesis frequently put forward in these days that the growth in social institutions lags behind the development of industrial and economic organization would find analogy in the monograph, *Physique and Health*, by Dr. C. Wroczynski.¹ He contends that man lags in acquiring physique and health. But the doctor, who is Chief Medical Adviser to the Ministry of National Education, Warsaw, is not as pessimistic as the Bishop of Calcutta who wrote, "every prospect pleases, and only man is vile." Apparently we seemed to be doing very well for some years, and then we began to slip. "Despite the strain of the changing conditions of life, it seemed that, thanks to the advance of civilization, the human body might develop towards a state of perfection. Most of the immediate dangers arising out of physical and social emergencies had been removed, the average length of life was increasing, the causes of early death were being overcome. All that remained then was to continue along the same lines."

But somehow or other we have failed to do so. From an extensive inquiry among scientific persons in 9 European countries, many data are assembled attesting to the physical deterioration of man. The number, kind, and range of physical defects among children and adults are presented; the percentages reported are disturbing. There are indeed too many mal-

nourished, rickety children in the world; needless dental caries, postural and muscular weaknesses abound; and the increase of nervous, maladjusted, and neurotic individuals alarms thoughtful persons. But the case is not strengthened by exaggeration. It is bad enough even if not growing worse; the evidence is not available that "man is undergoing profound and rapid biological changes." At all events Wroczynski thinks he is and inquires into the responsibility of physical education in the matter.

The rôle of physical education in the development of physique and in the correction of physical defects has a long and interesting history. The Ling gymnastics of Sweden arose in response to just these conditions that Wroczynski describes. We may agree with Voltaire that perfection comes slowly, but the purpose to use physical exercise in quickly rehabilitating degenerate man runs through the whole European effort in physical education.

Obviously there are two ways of looking at the biologic problems of human life. One is represented in Wroczynski's report. He writes, "Up to the present, modern methods and systems of physical education . . . have not produced on the health of the masses any effect demonstrable by statistical methods. To tell the truth gymnastics and sport are not practised on scientific lines." In the United States a similar view is voiced at times.

learn the never to be forgotten lessons that come from real experience with the creative forces of nature. It is possible to develop interests and skills in activities that enrich the whole of life, that habituate people to a way of life rather than to a concern for and care of muscles, bones, and bowels. Moreover, this approach is not blind to the facts. It would not ignore the defects of structure and function that are remediable by exercise. The corrective classes in schools and the restricted groups in colleges attest to the purpose and ability to use the therapy of special exercise when it is called for. But it would refuse to establish general educational policy based upon the limitations of abnormal children.

The extent to which defective structure and function is held as a standard is well illustrated by Roger's contention that competition in sports seeks to humiliate opponents and therefore should be abolished. It should be noted that while some persons may be humiliated when they lose, there is no humiliation unless a faulty education has taught them to expect to be always right and never to lose. Persons who are humiliated when they lose in games need special care exactly as do others who are timid, shy, secretive, unduly sensitive, fearful, and vain. To set a standard of social activity that is based upon the abnormal response of a player who is humiliated when he loses would correspond to establishing a diet based upon carious teeth and inability to masticate, or a standard of honesty based upon the behavior of a kleptomaniac.

It is obvious then that the educational approach for physical education does not ignore individual differences. It agrees with Labbé that physical education should consider the requirements of age, sex, and constitutional aptitude, and also the preferences, traditions, living conditions, and climate of a

country. There are some desirable norms in structure and function that can be used, but as Wroczynski points out the work on children is concentrated too largely on the first year of life, "as if normal growth were confined to that period." Research on functional norms is needed.

There are many interesting technical points presented. An American reader of this excellent monograph will be surprised at the recommendation that medical supervision of sport should be *introduced*. In the United States medical supervision of sport goes back to the early work of Hitchcock at Amherst that began in 1861 and widely prevails in colleges and universities today. But Wroczynski's argument for medical and scientific study of students, not only "to determine general fitness of each" but also "to bring to light his particular constitutional aptitudes" and needs point the way for progress in medical supervision in this area. Increase in height over several generations shows substantial gains for the Netherlands and the Scandinavian countries, and, using the army figures, the United States shows none. If, however, the data of American college men and women were used the improvement would be marked. It is refreshing to read the comment on breathing exercises: "It may be doubted whether deliberate aeration of the lungs is really useful," and Busing's opinion that for young people today, "foot gymnastics are more important than the respiratory gymnastics that are so generally employed and so highly recommended." Some day all physical educators in the United States will learn the simple physiology of the matter and will understand breathing in relation to function.

The conclusion that "an adequate range of free movements repeated several times during the day under natural conditions (not in classrooms),

is more effective (for growth) than any kind of artificial, indoor gymnastics," agrees with competent American medical and educational judgment. American coaches would do well to reflect upon the statement: "The one established point seems to be that serious competitive athletics are forbidden to boys under 18." We are more conservative in the United States with our girls and women than with our boys and men. Chailly-Bert and Bensidoun recommended high jumping for girls and women and the former advises 1,000 meter cross-country races for women. Neither proposal would be accorded agreement here.

The monograph is challenging; the range of topics discussed is wide; the European data are well sampled. Either physical education shall be organized on the basis of human defects or with respect to kinds of living that can go on. In the decision perhaps an American, most of all, would be helped by Lin Yutang's recent book, *The Importance of Living*. In any event

there are two attitudes in modern life. One leads to work, to factory, to office, to desk, with the hope of buying happiness with the money that is earned, and with unwarranted reliance upon special exercises to correct the physical deficiencies of life. The other attitude leads also to vocational effort that secures the necessities of independent, self-sustaining life, but around the margin are play and recreation that are also a part of life, just as vital as work that is needed to be done and that all wish to do. In this adventure in human living, physical education may always be an interpreter of living, an awakener of interests for leisure time, a teacher of skills that function, and a leader to the out-of-doors. It is for physical education to decide which road shall be travelled by man in the varied experiences of life. The gates are open. The highway is ahead.

EVERY year more than 77,000 stillbirths are registered in the United States. This number, however, represents only a part of the total number of fetal deaths, since registration of products of conception of periods of gestation before the 5th month is not required in most states. There are, in addition, more than 63,000 infant deaths annually that are due to natal and prenatal causes, 89 per cent of which occur in the 1st month of life. These serious losses of life in the fetal and neonatal periods are causing great concern, particularly in the presence of a low and falling birth rate. In connection with these problems it must be pointed out that the stillbirth rate has not decreased appreciably in recent years and that mothers whose infants are stillborn die much more frequently than mothers whose infants are live born.

Statistics issued by the Bureau of the Census do not, however, show the real magnitude of the problem. Registration of stillbirths is incomplete practically everywhere in the United States. There is no single definition of stillbirth in general use, and the period of gestation required by law in the different states for reporting stillbirths

varies widely. Furthermore, information with regard to causes of stillbirth is unsatisfactory because there is no acceptable classification of causes of stillbirth which include rules for assignment of cause.

Numerous reports dealing with causes of stillbirth are found in the literature, but their usefulness is limited because in only a very small proportion of them have comparable bases for analysis been used with respect to period of gestation and definition of stillbirth.

Because of the seriousness of the stillbirth problem and the lack of information on causes of stillbirths, the Children's Bureau in March, 1936, in coöperation with the Sub-committee on Stillbirths of the American Public Health Association, undertook a study of a large number of stillbirths occurring in hospitals. The objectives of the study were: (1) to obtain accurate data which would throw light on the causes of stillbirth and indicate methods for reducing the high mortality; (2) to develop a new classification of causes of stillbirth, including rules for assignment of cause. This report deals only with the first of these objectives. It is, of course, appreciated that although data obtained from hospitals are more complete than those obtained through ordinary registration, they are not necessarily representative for the country as a whole.

* A study by the Children's Bureau with the cooperation of the Subcommittee on Stillbirths of the American Public Health Association and individual hospitals.
** See instructions on reverse side.

On the face of the schedule (Figure I) prepared for use in the study appear certain items taken from the standard certificate now in use for the registration of stillbirths and additional items to obtain medical information essential for an understanding of the cause or causes of stillbirths. On the reverse side of the schedule are set forth the scope of the study with respect to the uterogestation, the definition of stillbirth and the instructions for entering information on special items. The period of gestation (20 weeks or more) used as a basis for the inclusion of a stillbirth in the study is that recommended for nation-wide adoption by the Sub-committee on Stillbirths of the American Public Health Association. The definition of stillbirth is that incorporated in Rules of Statistical Practice of the Association, namely*:

A stillborn child is one which shows no evidence of life after complete birth (no

breathing, no action of heart, no movement of voluntary muscle). Birth is considered complete when the child is altogether (head, trunks, and limbs) outside the body of the mother even if the cord is uncut and the placenta still attached.

Two hundred and twenty-nine hospitals in 49 cities in 26 states and the District of Columbia (Figure II) co-operated in the study by assigning a member of the medical staff to be responsible for filling in the items on the schedule for every stillbirth occurring in the hospital during the period of the study. The present report is based on the data obtained from 6,750 schedules received from these hospitals during the period February 1, 1936, to June 1, 1937.

From an analysis of the data on the schedules certain basic information has been obtained with respect to age and

TABLE I
*Time of Fetal Death with Respect to Labor
By Race*

	Total	Died Before Labor		Died During Labor	
		Number	Per cent	Number	Per cent
Total	6,367	3,713	58.32	2,654	41.68
White	5,162	2,908	56.33	2,254	43.67
Negro	1,135	766	67.49	369	32.51

parity of mothers, incidence of plural births, and sex and color of the still-born infants. As was to be expected in a study of hospital cases, it was found that the mothers were slightly older and that there was a greater proportion of primiparae and of white mothers than is shown by census reports on stillbirths. Data in regard to sex of the stillborn infants and in regard to the incidence of plural births were, however, in close agreement with census figures.

The stillbirths were studied (1) in

relation to whether the fetal death occurred before the onset of labor or during labor, (2) in relation to the period of gestation at which stillbirth occurred, (3) the method of delivery, (4) the frequency of certain complications of pregnancy and labor and certain conditions in the infants. The complications of pregnancy and labor were studied in relation to whether the physician recorded the condition as the cause of the stillbirth or regarded them merely as complications. Complete analysis of these data has not yet been

made, but information of major importance in the attempt to understand the causes of stillbirth can be presented at this time.

The necessity of determining whether the fetus was dead before labor began or whether it occurred during labor would seem to be clear if satisfactory analysis is to be made of the effect of such factors as the method of delivery, period of gestation or the various complications of pregnancy and labor. Table I shows that more than half of the total number of fetal deaths studied (58 per cent) were reported to have occurred before the onset of labor and that the proportion of deaths occurring before labor among Negro fetuses was somewhat higher than among white.

Table II shows the time of fetal death with respect to the onset of labor in relation to the period of gestation at which stillbirth occurred. In the earlier periods of gestation (20 to 27 weeks and 28 to 35 weeks) the proportion of deaths occurring before labor

began was greater than the proportion occurring during labor. In the later periods of gestation (36 weeks or more) a greater proportion of stillbirths occurred during labor. In this connection it should be pointed out that in more than one-third of all the cases in which the fetus was alive at the onset of labor, labor was prolonged more than 24 hours.

Whether the fetus was dead or still living at the time an operative delivery was performed has been determined for the stillbirths that were reported to have been associated with operative delivery. Table III shows that in the total series of stillbirths 40 per cent of the deliveries were operative and that operation was more common among white than among Negro women. Table IV shows, however, that the operation could not be held responsible for the stillbirth in a great majority of cases, actually 72 per cent, because in this proportion of the operative deliveries death of the fetus had occurred before the operation was under-

White	2,207	100	1,591	72	616	28
Negro	285	100	206	72	79	28

taken. The group of operative deliveries in which death of the fetus took place during operation, though representing 28 per cent of all operative deliveries, represents only 11 per cent of the total 6,750 stillbirths that have been studied. These facts make it clear that in the hospital cases here reported operative delivery did not play as important a rôle in causing stillbirth as it would have appeared to play if the time of fetal death had not been taken into consideration.

Although it is well known that certain complications of pregnancy and labor and certain abnormalities or other conditions in the fetus are often regarded as the cause of stillbirth, the frequency with which these same complications occur and are not regarded as cause has never been pointed out. Knowledge of the frequency of complication is basic to the determination of the rôle played by the different complications in causing stillbirth and will

be of value in developing a new classification that includes rules for assignment of cause.

In this study it has been found that those conditions entered on the schedules as complications of pregnancy or labor were entered also as causes of the stillbirth in a majority of the cases. When certain conditions found in the fetus were considered responsible for the stillbirth, they were always entered as a cause.

The incidence of the conditions studied and the frequency with which each complication of pregnancy or labor was reported as a cause, is shown in Table V.

Toxemia was the commonest complication of pregnancy found to be associated with stillbirth. It occurred in 1,601 of the 6,750 cases, 24 per cent of the total group. In 1,433 of these cases (21 per cent) the physicians indicated that toxemia was a cause of the stillbirth.

TABLE V

Frequency of Certain Conditions Associated with Stillbirth

	<i>Total</i>		<i>Mentioned as a Cause</i>		<i>Mentioned Only as a Complication</i>	
	<i>Number</i>	<i>Per cent</i>	<i>Number</i>	<i>Per cent</i>	<i>Number</i>	<i>Per cent</i>
Total	6,750	100				
Toxemia	1,601	24	1,433	21	168	3
Antepartum and Intrapartum Hemorrhage	1,285	19	1,059	16	179	3
Cord Complication or Anomaly	956	14	914	13	42	1
Congenital Malformation	531	8	531	8
Syphilis	510	8	451	7	59	1
Birth Injury	354	5	354	5

Hemorrhage, ante- or intrapartum, was the second most frequent complication, occurring in 1,283 of the 6,750 cases (19 per cent of the total). It was indicated as a cause in 1,069 cases (16 per cent).

Cord complications or anomalies (such as compression, prolapse, thrombosis, and so forth) were third in frequency, occurring in 956 of the 6,750 cases (14 per cent of the total). They were indicated as a cause in 914 cases (13 per cent).

Syphilis was recorded as a complication in only 510 of the 6,750 cases (8 per cent of the total) and as a cause in 451 cases. Since serological tests of the blood were made in only two-thirds of the cases, the exact rôle played by syphilis is not known. Ten per cent of the tests made were positive, 4 per cent among white and 28 per cent among Negro women.

Congenital malformation was recorded as a cause in 531 of the 6,750 cases (8 per cent of the total). It is of considerable interest that in four-fifths of the cases the malformation involved the central nervous system.

Birth injury was recorded as a cause in only 354 cases (5 per cent of the total), a figure that does not include congenitally malformed fetuses injured during birth nor those dead before the onset of labor which were reported to have been injured during birth. The fact that postmortem ex-

amination was made on only one-third of the total number of stillbirths studied probably accounts in part for the relatively small number of cases in which birth injury was recorded as a cause of stillbirth.

In order to evaluate properly the rôle played by these conditions and complications as causes of stillbirth it is important to consider them in relation to the time when the fetal death occurred with respect to the onset of labor and to the period of gestation at which stillbirth occurred. Obviously the death of the fetus before labor begins or death of the fetus in the pre-viable period must influence our interpretation of complications as causes.

Table VI shows that the fetus died before labor began in more than half of the cases in which toxemia, hemorrhage, and syphilis were complications of pregnancy and in which congenital malformations were found in the fetus (65, 58, 82, and 60 per cent respectively). On the other hand, in those cases in which cord complications and birth injury was reported fetal death occurred during labor in 61 and 100 per cent of the cases respectively.

Table VII shows for each condition the period of gestation at the time of delivery. The periods of gestation used are the period 20 to 27 weeks, which includes pre-viable infants; the period 28 to 35 weeks, which includes infants

TABLE VI

Time of Fetal Death with Respect to Labor By Condition Associated with Stillbirth

Birth Injury	376	11	3	29	8	336	89

viable but premature; and the period 36 weeks and more, which includes term and overterm infants. Twenty-six per cent of the stillbirths associated with hemorrhage, 22 per cent with syphilis, and 13 per cent with toxemia occur during the previable period. Nearly two-thirds of the stillbirths associated with syphilis and with hemorrhage, and more than half of those associated with toxemia occurred prior to term. On the other hand, most of the cord complications (75 per cent), congenital malformation (55 per cent), and birth injuries (89 per cent) were found when the fetus was full term.

Perhaps the most important point to consider in this study, aside from the preparation of a new classification of cause of stillbirth, is how many of these 6,750 stillbirths were preventable. Stillbirths caused by syphilis are, of course, the most easily prevented. Serological tests of the blood for syphilis were made in only two-thirds of the cases studied (68 per cent) and in more than a third (36 per cent) of the cases in which a test was made it was not made until the day of delivery or later. More than one-half of the total number of women were, therefore, either not tested or were tested too late to have been treated if they were syphilitic. If all the women who were known to be syphilitic and who gave birth to syphilitic fetuses had been

adequately treated for syphilis throughout pregnancy, 451 stillbirths or a large proportion of them could have been prevented.

Adequate prenatal care might have prevented or reduced the severity of a considerable proportion of the 1,433 cases of toxemia. It is well known that the number of stillbirths occurring in hospitals is increased by the admission of women acutely ill with toxemia and eclampsia who have had no prenatal care or who have had inadequate care. In nearly 200 cases, or 12 per cent of all toxemias, the diagnosis was eclampsia. That this condition can be controlled in a great majority of cases by giving adequate prenatal care is well recognized and many other cases of toxemia also are amenable to treatment. To expect a reduction in the number of stillbirths from this cause seems reasonable.

The prevention of stillbirths due to ante- and intrapartum hemorrhage is more difficult because knowledge of the causes of the underlying conditions is incomplete. However, in a certain proportion of these cases immediate hospitalization and proper treatment would probably be effective, since a large proportion of the cases were recorded as due to premature separation of the placenta, and only somewhat less than one-quarter were cases of placenta previa, a condition obviously not pre-

they are gaining well. In selecting the definition of intermittency to be used, a question arises as to whether some part of the year should be omitted in the use of intermittency, or whether different standards of intermittency should be used for different seasons of the year. It is believed that intermittency should not be determined in June for the following reasons:

1. The closing of the school year commonly makes the weighing date earlier so that the May-June period is likely to be less than a full month. (This was the case in many of the classrooms from which our data were collected.)

2. Since it is near the end of the school year, special attention for poorly growing children is not possible over any continued period.

3. This is a time of year when the seasonal effect upon gain in weight is most keenly felt and has assumed increasing importance as a cause of poor growth.

The greatest difficulty or weakness of any growth index is seasonal fluctuation. However, it is not deemed wise to use other standards for earlier months of the school year because, as is shown by Chart A, the next lower standard, a 2 month intermittency, would give us disproportionately high percentages of children.

We do not yet have enough data to know whether cities or schools with good health programs have less intermittency than others. Groups of a few hundred children studied from other cities show a somewhat higher percentage of cases screened than at Malden.

The data here presented touching upon seasonal growth apply only to climates comparable to that of New England. It seems unlikely that it would apply to southern states.

RELATIONSHIPS BETWEEN INTERMITTENCY AND POOR ANNUAL GROWTH

Many school systems give attention to children who have shown poor annual growth. Because of this practice

it seemed practical to explore the relationship between poor growth and intermittency. Poor growth during the school year was determined for the lower decentile of a gain distribution for each age group. Table IV shows the percentage of overlapping between poor growth for the school year and intermittency by the 3 month period, third method, with June weights omitted. This clearly shows that poor growth for the school year and intermittency are far from identical. The amount of overlapping approximates 25 per cent. There are apparently many slowly growing children who do not stop growing for 3 months.

The question arises: Does either intermittency or poor growth for the school year select children on a size basis rather than on a health basis?

We can determine this by comparing the weights of the children selected with the weights of the whole school population. From Table V it can be seen that the poor growth method, like the height-weight-age tables has a tendency to select children who are

naturally small for their age; the intermittency method does not. Intermittency would thus seem to be a definitely better health screen since it is not influenced by the size of the child.

It must be recognized that inter-

TABLE V

Comparison of Average Weights of the Children Screened with the Average Weights of the Whole School Population

Items	Pounds Less or Greater than the Ave. Wt. of All Pupils	
	Sex → Boys	Girls
Pupils Screened by the Proposed Intermittency Method	+ .272	— .500
The 10% of the Pupils Having the Smallest Gain for the School Year	—2.32	—2.25

mittency is not a diagnosis of a specific condition. It selects children who in general have greater need of special attention for one cause or another than the children who are growing well. We are not yet in a position to say that 3 month intermittency cannot occur in a child with relatively good health. We are in a position to say that the use of such a screen is simple and that it secures attention for many children who need it and profit significantly by it.

SUMMARY AND CONCLUSIONS

The most practical public school procedure for screening children who grow poorly during the school year is as follows: Weigh children every month of the school year except June and record intermittency where there is no gain or a loss for each month of 3 successive months.

The number of children screened per school year will approximate 10 per cent while the number of intermittency cases will be in the neighborhood of 12 per cent. In other words, one might expect 2 per cent of the children to be picked up more than once.

Seasonal variation in growth is a factor contributing to a small amount of intermittency in the fall and a

gradually rising amount as the school year progresses. It does not seem wise, however, to use a different standard of intermittency at different seasons.

The evidence presented indicates that poor growth for the school year cannot be substituted for the recommended procedure of measuring intermittency. The identity of the two are not the same, and furthermore the former has the tendency to select children of small skeletal build.

School experience and other studies² indicate that it is worth while for the teacher, the nurse, and school doctor to investigate the cases of children who have stopped growing for long periods—investigating (1) poor habits or recent illness, because of which they may need a modified program, (2) serious physical defects which need correction.

This study shows clearly that if intermittency in growth is to be used as a screen, we need a standard definition. The definition here proposed seems the most practical.

Monthly weighings are necessary to use intermittency as a screen as they are also desirable to get the best educational value from using growth as an incentive toward healthful behavior.

On Being a Good Egg

THERE'S nothing new in the idea that to get along well in life one must be a "pretty good egg." But the idea that one must start from "a pretty good egg" to get well along in life—that, in the popular vernacular, is something else.

Such a start, according to Professor Raymond Pearl, noted biologist of Johns Hopkins University, is one of the most important factors in the achievement of great longevity. In a lecture on the search for longevity, the fifth of a series delivered to the laity of the New York Academy of Medicine, he said that the rôle of heredity in a long life span has been demonstrated. Reporting his remarks in its issue of February 25, the *New York Times* states that data have been compiled from life tables for parents of very long-lived persons compared to life tables for parents of very short-lived persons: from life tables of children of short-lived parents, mediocre parents in respect of longevity, and long-lived parents: and from the ancestries of nonagenarians and centenarians compared with ordinary folk of mediocre longevity. They show that nonagenarians and centenarians have a much higher proportion of long-lived im-

mediate ancestors than does run-of-mine humanity.

It has been shown also that in the case of persons destined to die of the cardiovascular diseases, the so-called diseases of civilized man, it is possible to demonstrate on the basis of certain medical, genetic and other examinations made when the persons are in a state of health, that groups that will be short-lived and groups that will be long-lived can be distinguished and differentiated years prior to the onset of the diseases that eventually will kill them.

Professor Pearl also presented "the first life tables ever constructed" on the relation between tobacco and longevity. They show that smoking is associated with definite impairment of longevity. As for alcohol, while no measurable effect of the moderate use of alcoholic beverages on longevity can be demonstrated, heavy indulgence definitely and considerably impairs life expectation.

Hard physical labor, whether performed in or out of doors, has no effect upon life expectation up to about the age of forty. After that age, however, such labor definitely and considerably impairs longevity.—*Health News*, N. Y. State Dept. of Health. Mar. 7, 1938.

THE NEED FOR A NATIONAL HEALTH PROGRAM

REPORT OF THE TECHNICAL COMMITTEE ON MEDICAL CARE

AN annual bill of ten thousand million dollars commands attention even in these days when government thinks in billions. The Technical Committee on Medical Care of the President's Interdepartmental Committee to Coördinate Health and Welfare Activities believes that this bill can be cut in two by supplementing existing medical resources and effecting their more even distribution.

In a report just made public the Technical Committee presents clearly and concisely the facts brought out by recent studies of the nation's health, the means available for its protection and the services at hand for the care of the sick. Due tribute is rendered to scientific advances in medicine and in public health procedure. At the same time the committee stresses the lag in practical employment of the new knowledge to provide equal health service to the whole people. For this two causes are given, lack of adequate funds and the need of well trained personnel. A primary objective of the committee's report is to show what can be done, in the light of what is now being done. It reviews the achievements of the past in the various fields of preventive medicine, applauds the results attained in some, but lays emphasis on unmet needs in the two broad classes—maternity, infancy, and childhood on the one hand, and on the other specific causes of sickness, disablement, and death not associated with the risks of early life.

Among approximately 2,000,000 annual births, 75,000 infants are stillborn and 69,000 die in the first month of life, while 17,000 mothers die each year from causes directly connected with childbirth or from intercurrent diseases aggravated by pregnancy. Lack of adequate medical attention is evident in many of these tragedies. In one year a quarter of a million women had no doctor at time of delivery; only 2 of 49 state health officers reported facilities for maternal care in their states as adequate; in urban areas 71 per cent of births occurred in hospitals, and in rural areas 14 per cent; prenatal and child health centers were adequate in but few localities, totally lacking in many; especially

in rural districts nursing service was woefully inadequate. These are samples of unmet maternity needs.

Certain specific inadequacies are similarly listed in provision for preventive and corrective care of children. The use of protective measures against communicable diseases falls far below its possibilities. Less than half the preschool children were immunized against diphtheria in two-thirds of 77 cities and counties recently surveyed. The report criticises severely the ineffectiveness of the health care currently provided for children in the elementary schools. Even less satisfactory is the dental care of our youthful population during its growing years.

Health hazards of later years are also reviewed at length in the report of the committee. Tuberculosis, venereal disease, pneumonia, malaria, chronic diseases of middle and old age, mental afflictions, and industrial risks are discussed and flagrant omissions in existing programs for their prevention and care are indicated.

Following this succinct and well supported statement of the shortcomings of medical care in the United States the report turns to a consideration of causes. Low income groups show notable lack of adequate medical service and at the same time greater percentage of need due to higher morbidity rates. The National Health Survey has shown that families with incomes less than \$1,200 average 8.9 annual days of disability per person, while families with incomes above \$3,000 show only 3.8 days of such illness. Furthermore, 40 per cent of the families investigated were in this low income group. One in every 20 heads of family in the relief group was found unable to work because of chronic disability as contrasted with 1 in 250 heads of family where income was \$3,000 or more. Children in relief families lost 30 per cent more time from school than those in moderate and comfortable circumstances.

The need for medical care, therefore, is plainly greater in relief and low income groups. Actual distribution of medical care to these groups, however, is less than to those who can afford to pay. The myth that the very poor and the rich get about equally good medical care is exploded. This is true only in rare cases where exceptional hospital provision is available for the poor. A carefully prepared table shows that the well-to-do get about $2\frac{1}{2}$ times as much medical care as the poor although the latter's need because of serious illness is $2\frac{1}{4}$ times as great. Further evidence of lack of needed care is furnished by the fact that 47 per cent of the members of families in the \$1,200 or less income group receive no medical, dental, or eye care during a year in contrast to 24 per cent in the \$5,000 group and 14 per cent in the \$10,000 income families. There is no escape from the conclusion that individuals in the low income group, while needing definitely more medical care, actually receive substantially less than those in families comfortably off or wealthy.

Attempts at budgeting for illness by low income families have been frustrated by the unpredictable demands. A family may be stricken in a single year with a staggering load of sickness which its resources are wholly unable to bear. The committee is unanimous in the belief that measures to lighten these unpredictable medical costs are needed by families with low incomes even though such families are ordinarily self-sustaining in other essentials of living. It is also convinced that considerably larger financial support is needed for the medical care of those submerged families without income or with incomes insufficient to provide the economic necessities of life.

Remedies for present inadequacies in medical care of the entire population

are laid down in principle without prescribing a specific plan. Obviously provision must be made for adequate professional personnel. At present there would appear to be approximately enough physicians and private duty nurses to care for the country's need. Some 3 times as many public health nurses as are now available are indicated while the number of dentists could well be doubled without reaching the saturation point.

Hospitals are inadequate both as to number and equipment. It is estimated that 400,000 beds should be added to the 1,100,000 now available.

The critical aspect of the problem, however, lies in the matter of an even distribution of services considering the country as a whole. Physicians show an urban concentration. Rural areas are more in need of dentists and private duty nurses than are cities. But the rural lack of public health nursing reaches a point of scandal in certain localities. In addition to the personal preferences of professional men and women there is a vast economic problem to be met if equal opportunities for medical care are to be supplied all parts of this country. Some plan of subsidy through local taxes, insurance, government grants-in-aid, or a combination of all three, appears clearly indicated.

The committee recognizes that we have at our command tried and tested methods which if put fully to use could accomplish vastly more in the prevention of suffering and the conservation of health. Progress is discouragingly slow under present methods and policies. Better organization of existing resources and further additions to supply evident deficiencies are recommended. "The committee finds there is need and occasion now for the development of a national health program."

The Technical Committee on Medical Care has presented a masterly condensation of the vast store of information on the subject resulting from recent surveys. This has been brought into reasonable and readable form. Conclusions are implied rather than stressed. It leaves no doubt in the mind that the status quo is unsatisfactory. It proposes no revolutionary policy. On the other hand its method is to appraise fairly the merits of procedures now in operation, and at the same time to point out their inadequacies. It advocates essentially the balancing of resources now available by supplying deficiencies where the need is apparent in the various aspects of medical care. It sets forth the highly reasonable doctrine that coördination of these resources is an essential element in their successful employment.

"IT CAN'T BE DONE UNDER OUR LAW"

THE procedure of health administration is to a considerable extent dictated by the law. The legal prescriptions are desirable to the extent that they are necessary for the sake of insuring coöperation of the citizen on one hand, and of protecting him against bureaucratic oppression on the other. But many procedures have been incorporated into the public health law which should have been left to the common sense of the health administrator, or to a small body of qualified persons included in a board of health or an advisory council.

Many of these laws which were thoroughly consistent with the public knowledge of their day, have subsequently become antiquated in that they place unnecessary burdens upon the public, or dictate unnecessary procedures for the health administrator. Some officials, who would like to modernize these laws, hesitate to go before the legislature because, in the endeavor to secure repeal of

obsolete provisions, they run the risk of subjecting the essential provisions to tampering, as has happened in more than one instance.

Among the more antiquated laws are those relating to vital statistics. The model vital statistics law which was drawn up about 1908 performed a very useful function, but it has now become obsolete in a number of respects; and in most of the states, the vital statistics codes today operate as a serious barrier to progress. Any proposal to improve the vital statistics procedure is exceedingly likely to evoke from a number of registrars a statement to the effect that: "Our state could not coöperate in this movement; it is contrary to our state law." And with many, the matter ends there. This mental attitude is unfortunate, and is frequently unjustifiable.

It is, of course, frequently true that in some states the legislative barriers may be insuperable in a practical sense. The attitude of registrars toward their laws, however, is often unnecessarily fatalistic, and the primary purpose of this editorial is to emphasize that the law is not always as rigid as the registrar imagines, and that it should never be assumed that a desirable step cannot be undertaken until the law has been examined in a constructive attitude. This attitude is reflected by the question "Under what provisions of the law might the proposed procedure possibly be *permitted*?" as opposed to the question "What does the law *forbid*?"

If the law be approached in this attitude, it is really remarkable how much can be done, even with an antiquated law. As an example let us take the proposal recently approved by the Association of State Registration Executives that burial permits issued in one state be accepted by cemetery authorities in other states (whence the permit would be relayed for the record and information of the local registrar). Under many of the vital statistics laws, this procedure might be contested on the ground that the state law provides that no body shall be buried within the state unless a proper death certificate has been deposited, and a burial permit obtained. Under a narrow interpretation of the law, the acceptance of foreign burial permits might be barred; but under a liberal one it probably would not. Moreover, there is frequently a provision that the state board of health shall have authority to regulate the transportation of bodies, and under this provision a favorable regulation might be made by the State Board of Health.

Again, in one state the law forbids the issuance of information from birth or death records by the county health officer to persons not authorized. But it was found possible to give out simple age statements on the ground that these did not give out new information, but merely confirmed the statement given by the applicant in his request.

If appeal is made to an attorney-general in such matters, the outcome will depend to a very considerable extent upon the manner in which the question is phrased. A bald request for a decision as to the legality of the proposed move may very readily result in a negative ruling. If, on the other hand, it is pointed out that the proposed move would be for the general welfare, that there is general support and no visible opposition, and if the references to the law include the favorable sections, the Attorney-General will usually be found willing, in his ruling, to give the benefit of any doubt to the progressive cause. This is entirely ethical and proper. No group of legislators can possibly frame a law which foresees all contingencies and social changes, and it is certainly unsound for any public servant to interpret doubtful points in the law to the detriment of the public, whose welfare the law is intended to serve.

A revision of the vital statistics laws of our states is certainly in order. The president of the American Association of State Registration Executives has initiated steps toward reorganizing the model law, but reform will probably be a slow process. In the meantime, before it is concluded that "It can't be done under our law," an effort should be made to see whether the impossibility claimed is as real as it seems.

THE SO-CALLED HUMANE POUND LAW IN CALIFORNIA

THERE is no such thing as a local antivivisection fight, though such movements are staged locally in the various legislatures of the country. One fight is going on now in Washington, D. C., which legally affects only the District of Columbia. What seems to be a more important movement is going on in California in what is called the Humane Pound Law. In 1922, the antivivisectionists carried on a big fight, since which time they have been fairly quiet. The recent movement, beginning in 1937, has been carried out under the initiative which the California law provides. A petition has been circulated which has received the necessary number of signatures, and the matter will go before the voters on the 1938 ballot. While the law provides that dogs and cats shall not be delivered to medical schools from public pounds, it is perfectly plain that this would greatly cripple the use of animals in experimental medicine. The election will not take place until November 8, 1938, but it is not too soon for those interested in scientific medicine to take steps to frustrate the ends of these misled people.

Fortunately, in 1915, the California Society for the Promotion of Medical Research was organized and was the leader in the successful campaign against the "antis" in 1922. It has again entered the field and will doubtless do effective work. We cannot do better than to quote here a resolution adopted by the Western Society of Naturalists:

Resolution adopted, at the request of the California Society for the Promotion of Medical Research, by:

"The Western Society of Naturalists, meeting in Berkeley, California, December 28, 29 and 30, 1937, records its emphatic opposition to any measure such as the proposed 'State Humane Pound Law' which will hinder or curtail animal experimentation as conducted by those fully qualified in biology and medicine. It is the belief of this Society that the present level of health and humane protection of man and animals and further advance in our knowledge of the phenomena of life can be maintained only by constant vigilance and by continued study of the nature of vital processes through the experimental investigation of living animals. Every effort should be made to provide the necessary animals for scientific studies rather than to interfere by the passage of hampering legislation."

While the American Public Health Association as such has not taken any steps in this matter, there is no question that we can assure the California people we are with them heart and soul, and will support them to the best of our ability.

"NINETEEN THIRTY-SEVEN A STAR HEALTH YEAR"

TWO heartening reports have already been made this year.^{1,2} The first is from a selected group of 17,700,000 industrial policy holders for the year 1937. The second covers reports from 39 states of the Union and Hawaii for the first 9 months of 1937. One would expect the selected group of policy

holders to make a better showing than the general population. However, the two reports run very closely parallel and agree essentially. Nineteen thirty-seven was a "year of best records." For the selected group the mortality rate for all causes of death combined was 8.221 per 1,000, or 2.1 per cent better than the figure for 1936. For the entire population the mortality from all causes was 11.1 per 1,000, or 6 per cent lower than that for the same months in 1936. For the insured, 8 causes of death—typhoid fever, scarlet fever, tuberculosis, chronic nephritis, diseases of pregnancy and childbirth, homicides, accidental burns, and railroad accidents showed the lowest mortality rate for all time in the insured group, and the combined rates for all forms of accidental death was lower than ever before. In the general population, whooping cough, poliomyelitis, influenza, cancer, and diabetes showed an increase over 1936. All other causes of death gave rates which were not above those of 1936, and mostly lower. All of the important causes of death except heart disease, pneumonia, and cerebral hemorrhage gave the lowest rate reported for 4 years past.

Particularly striking is the death rate from tuberculosis. The decline which has been noticeable for a number of years, though checked in 1936, has continued during the first 9 months of 1937, being for that period, 50.7 per 100,000, or 2 per cent less than for last year. In the insured group, the mortality from tuberculosis dropped 5.5 per cent. Both among the insured and in the general population the drop in the death rate from tuberculosis is considered as "probably the greatest single achievement in the entire history of the public health movement."

While in the daily press we see frequent warnings that the liquor interests are running wild and encouraging the use of liquor to such an extent that a general movement for the reënactment of prohibition is likely to occur, the Metropolitan Life Insurance Company reports that the death rate from alcohol among its policy holders is at its lowest point since 1921: only 323 deaths among 17,700,000 persons. Of course this is a selected group to begin with, and is under some control. Nevertheless the report is heartening.

Among the general population there has been a continued decline in deaths associated with pregnancy and childbirth, a decline which has been going on for 9 consecutive years. Among the insured there has also been a continued drop in the death rate among children, adolescents, young adults, and even among those of all ages up to 65. For 1937, the death rate was less than one-fourth of that prevailing in 1911, when the Metropolitan Company began its Health and Welfare Program.

In spite of these favorable reports which are most encouraging and prove the value of general health work, there is no disposition to become careless and contented. Indeed campaigns against some of our most important diseases such as influenza, pneumonia, and syphilis are going on with a vigor never before manifested, and there is evidence of the most gratifying response on the part of the public.

PUBLIC HEALTH EDUCATION*

An Award for You: An Idea for Others—Again, as in years past, awards will be made for distinctive presentation or interpretation of health and welfare topics. Each year a group of health agencies has won the attention of the judges for attractiveness and effectiveness.

For 1938 the awards will be given for examples of writing: newspaper news releases or feature articles; booklets; letters appealing for funds, answering questions, or replying to criticisms or complaints; reports; articles in official organs of state or local groups, such as clubs, unions, churches, etc.; or other forms of writing to be read, not for broadcasts, plays, etc.

Examples should arrive by April 15, 1938, addressed to Awards Committee, Social Work Publicity Council, 130 E. 22d St., New York, N. Y.

Will the state department and the state association check quickly the sources of good health writing in their states, and try to get samples sent to New York? Likewise we hope that our readers will use the telephone to dig up good examples of the home writing product.

The Office of Public Health Education—Not in years has any single development meant so much to public health education as the inauguration of the Office of Public Health Education in the U. S. Public Health Service. Hence we quote quite fully from *The Health Officer* for Jan., 1938:

Assistant Surgeon General Robert Olesen announced on December 6 that Philip S.

Broughton, Informational Assistant of the Venereal Disease Division, had been assigned by Surgeon General Parran to take charge of the Office of Public Health Education. Mr. Broughton replaces Dr. R. R. Spencer, now Executive Assistant to the National Cancer Institute.

The Office will remain under the direction of Dr. Olesen as a part of the Sanitary Reports and Statistics Division which is, indeed, a division of health information. The primary objectives of the Office of Public Health Education, Dr. Olesen said, will be to demonstrate by precept and example the modern technics of health information. Emphasis will be primarily on the presentation of publications for the layman, attractive not only in content but in format as well. Informality of style, typography, illustration, color, and other means necessary to catch the eye will be developed in these publications. A large part of the work of the Office will be the preparation of materials for other divisions and individuals of the Public Health Service, and may extend to the preparation of exhibits. One of the first objectives of the Sanitary Reports and Statistics Division for this year will be the revision and bringing up to date of previous publications of the Service.

The Health Officer—first publication of the Office of Public Health Education—will continue to be issued on the present basis. Mrs. Elizabeth G. Pritchard, who has been with the Office since its establishment, will act as Editor.

The Health Officer began with a monthly circulation of 1,000. No efforts have been made to increase the circulation, but through requests to the Surgeon General, the mailing list now totals 2,299. The publication is available free of charge, upon request, to the personnel of official and nonofficial public health agencies, social welfare agencies, and personnel of educational departments and institutions, as well as to libraries. Owing to the obvious limitations of a gratis publication, the circulation is limited and regulated by order of the Surgeon General. Upon his approval, representatives of the above mentioned organizations may be placed on the mailing list.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

How Many Public Health Educators Are There?—Who knows the answer? *No one!* But, with a little help from the field, we are about to get the answer.

The Department of Social Work Interpretation, Russell Sage Foundation, has undertaken a census of positions in health and social agencies which are concerned with adult education, interpretation, public relations, or publicity.

A brief questionnaire is being distributed with the coöperation of national agencies with which are affiliated some 10,000 organizations. To secure comprehensive covering of the health education field, readers of these pages are urgently invited to ask for a census blank, and to volunteer to get blanks filled out by other health educators in their cities or states. Please write to Mary Swain Routzahn, Russell Sage Foundation, 130 E. 22d St., New York, N. Y.

Following the census there will be studies of what preparation is needed, and how it may be secured. The several inquiries will cover those who give their whole time, or a considerable share of time under such titles as director or secretary of health education, publicity secretary, editor, staff writer or artist, or who have to do with printed matter, newspaper releases, motion pictures, exhibits, radio, and so on. All but the clerical or office staffs will be included. Geographically the study is limited to the United States.

Even a mere listing of the actual health education workers in itself would be of great interest, and of considerable value.

Health Education De Luxe—

At a dollar a throw a large, influential constituency is getting a sound course in highly significant health topics. *Fortune*, 135 East 42d St., New York, N. Y., the dollar a copy magazine.

has presented the following subjects in 1937-1938 to date:

March, 1937: "Cancer, The Great Darkness . . . which engulfs 135,000 lives per year."

November, 1937: "Death Comes to the Average Man . . . via the heart and the arteries, which kill more people than cancer, tuberculosis, nephritis, and pneumonia put together."

January, 1938: "The Accident of Birth." . . . "A \$250,000,000 industry is scrutinized for 'social responsibility' and is found to be in need of some drastic legislation—one way or the other . . . This article is being published in the interests of the health and well-being of persons who are exposed to the products of the birth control industry. It is NOT a discussion of the technics of contraception. It has been read and endorsed by Dr. Morris Fishbein, editor of the *Journal of the A.M.A.*, and by Dr. Paul Nicholas Leech, Secretary of the A.M.A. Council on Pharmacy and Chemistry."

Health Education in Journal, Feb., 1938—References in *American Journal of Public Health*:

"Health Education for the Millions," by Dublin and Calver (pp. 117-122): about health and medicine at New York World's Fair.

In "Syphilis Control in Industry," by Sayers, p. 155 and 156):

Is the campaign against syphilis going to be a nine days' wonder, another thing that "something ought to be done about," or will it be translated into definite programs? . . .

Industry with its compact organization will find the development of a vigorous education program profitable. . . .

Industry might extend that educational campaign into the field of prophylaxis.

In "The Rôle of the Nurse in the Control of Syphilis and Gonorrhea," by Crain (pp. 181 and 182):

The attitude of the worker . . . is fostered by education, and the development of a scientific attitude toward these disease problems. It becomes crystallized as the worker acquires a deep respect for personality, a growing ability to see situations through the eyes of the patient, an aptitude for building on strengths rather than weaknesses, and a profound faith in the powers of persuasive

teaching and the futility of the weapons of fear and force.

It cannot be too strongly emphasized that effective work in syphilis and gonorrhea control requires informed, well trained workers. Education on the job, through institutes, staff education, and summer school courses, must be accepted as a necessity, and improvement and enrichment of courses in training schools should be stimulated.

(See also "Education" on page 182.)

In "A Suggested Program of Control of Amebiasis by Health Departments," by Craig, the program of control includes (page 192)

The education of the public regarding the infection and its importance as a public health problem, by means of printed information, radio talks, etc

"Journal Policy," an editorial statement in pages 198-199, is of importance to every reader.

School health educators will note the book review on page 221.

"A Selected Public Health Bibliography" (pp. 222-224), as always includes material of interest, as does "News from the Field" (pp. 229-235).

Radio Censors Cancer Education
—As reported in *Bulletin*, American Society for Control of Cancer, 1250 6th Ave., New York, N. Y. (Feb., 1938):

The problem of what may and may not be said about cancer on the radio continues to present difficulties to speakers: Michigan reports through Dr. Henry J. Vandenberg that radio stations in the state have adopted a liberal policy in keeping with the modern tendencies and now permit the mention of womb, rectum, and breasts. From St. Louis a speaker says that she was not permitted to use the words "breasts, uterus, or body openings." It would be valuable for the American Society for the Control of Cancer to receive reports from physicians who have had similar difficulties on what they are not permitted to say over their state radio stations.

"The Health Officer," Dec., 1937
—This monthly is published by U. S. Public Health Service.

"Dr. Nash's Cookery Book" (an English health officer writes a cook book for cutting the cost of good food) . . . Youth fights syphilis (what the Y.M.C.A. is doing) . . . Syphilis control training at Harvard (a full year course) . . . The informative content of education by H. G. Wells (condensed from *Survey Graphic* for Nov., 1937).

"The Health Officer," Jan., 1938
—This issue of the magazine issued by U. S. Public Health Service contains material on health education:

"WPA adult education project issues sample health kits" (sample collections of health material and list of sources supplied for use by state and local adult education groups).

"Public relations for public health" (by Bleeker Marquette, first given at the A.P.H.A. meeting in New York).

"Dental health" (health education for the profession, with announcement of American Assn. of Public Health Dentists).

In "News Briefs" a number of paragraphs on health education.

Hygeia for March, 1938—Published at 535 N. Dearborn St., Chicago, Ill., at 25 cents a copy.

Syphilis . . . How to blow your nose . . . Heart murmurs . . . Eyes and the office worker . . . Nurses in the making (picture scenario of a movie) . . . Tuberculosis and literary genius . . . Infections (little dangers) . . . Leprosy . . . Parasite tricks ("the tramps, loafers, and sharpers of the biologic world") . . . Fatigue and rest . . . The amebas (a doctor's armchair story to Sonny) . . . Health teaching helps by radio and April to June announcements of A.M.A. broadcasts . . . New books on health . . . Questions and Answers.

In "School and Health" by J. Mace Andress:

Building the health curriculum in the high school . . . All in the day's work (Syracuse) . . . Body building and regulating foods (iron and iodine) . . . Seeing is believing (where to get films and other visual material).

WANTED

Reprints about health education; samples of health education printed matter, broadcasts, etc.; copies of

house organs and magazines; catalogues or lists of graphic materials, publications, etc., are invited by Dr. A. Chavarria, Secretaria de Salubridad Publica Y Protection Social, San José, Costa Rica.

BULLETINS OR ORGANS

Second class mail is used for some state and local bulletins, 3d class for others. If those who have been unable to secure second class privileges will report that fact to the editor of this department consideration will be given to what may be done about it.

Young looking and vigorous is *Michigan Public Health* which with the Jan., 1938, issue

... begins its 41st year of continuous publication as the official bulletin of the Michigan Department of Health. It is with pardonable pride that we look back over this lengthy historical panorama of public health activities in Michigan. . . .

This publication is probably one of the oldest continuous bulletins published by a state department of health. First issued in 1898, just 25 years after the creation of the original Michigan State Board of Health, the bulletin continued for 3 years as a monthly publication under the title of "Teachers' Sanitary Bulletin." In 1906 it was changed to a "Public Health Quarterly." The bulletin was again issued on a monthly basis in 1913 and the current Volume XXVI is numbered from that date.

It seems entirely fitting that *Michigan Public Health* should begin the New Year in a new dress. We thus go modern in a revised format. The cover is the work of Miss Pearl Turner, staff artist of the Bureau of Education. The two column type page, the headings, captions and type styles should make for a more effective and pleasing presentation of subject matter. The new format, however, will not lessen our emphasis on content. *Michigan Public Health* will maintain those standards of worth which have made it an important medium of health education in this state for four decades.

Back issues of *Chicago V. D. Bulletin*, Board of Health, Chicago, Ill., quickly go out of print. And

Since it is not possible to supply past issues, it is planned that the 6th month's issue

will carry reprints of some of the matter that has appeared in the previous five, about which most inquiries have been received. The December issue, therefore, will contain a reprint of all matter previously published, in answer to queries concerning the Marriage Law Examination—the Chicago Plan of V. D. Control—the outline of treatment of syphilis—information concerning service offered by the Board of Health—etc.

Quoted from *Health Bulletin*, North Carolina State Board of Health, Raleigh (Feb., 1938):

In this issue of the *Health Bulletin*, we present to our readers who reside outside the state, some of whom live in every state in the Union and in every civilized country in the world from Ongole, India, to Labrador, two comparatively new views of the North Carolina scene in the beginning of the year 1938.

Delaware Health News, State Board, Dover, went red in winter, 1938, number. Something in red on front and back covers, and on alternate pages throughout.

Did we call attention to the fact that *Venereal Disease Information*, after being mimeographed 18 years, now comes in printed form? U. S. Public Health Service, Washington, D. C. 50 cents, a year (send to Supt. of Documents, Washington, D. C.).

Georgia's Health, State Dept. of Public Health, Atlanta, is one of the bulletins or house organs which holds a blank space on the back page upon which is stenciled the addresses to which it is mailed.

In *Arizona Public Health News*, State Board of Health, Phoenix:

"While the contents of the magazine are not copyrighted, credit is requested wherever material is used."

Monthly Bulletin, Indiana Board of Health, Indianapolis, comes in a new dress—a brand new cover with space for a photograph and mention of leading articles.

News Letter, California Tuberculosis Assn., 45 2d St., San Francisco,

appeared in February in printed form.

We are always glad to see the selected copy from various sources which appears in *Bulletin*, Dept. of Health, Lincoln, Neb. But every time we wish that the editor would drop the word "Exchanges" and the odd ornament which appears above it in every issue. The use of "Exchanges" once was common enough in rural newspapers, but many of today's readers will not understand its meaning in the *Bulletin*. And it is not needed.

A book in Chinese is reviewed in *Public Health Reviews*, Ann Arbor, Mich. Oct. 15, 1937. "Health Education in Kindergarten," by Zong Chow. Published by Commercial Press. Under stress of a common editorial convention, the omission of the city of publication, we are left to guess that this book was issued in Shanghai, or was it Hong Kong?

"Browsings" heads a corner in *Monthly Bulletin*, Indiana Division of Public Health, Indianapolis. Both articles and books are briefly mentioned.

"Diabetes" is subject of an entire issue of *Iowa Public Health Bulletin*, Des Moines, Oct.-Dec., 1937.

Diabetes was the central theme of *Commonwealth*, Massachusetts Dept. of Public Health, Boston. Apr.-June, 1937. 78 pages on diabetes; 6 pages on departmental matters.

"A few false advertisements from current publications" are reproduced in miniature on the cover of *Birmingham's Health*, Birmingham, Ala. Feb., 1938. In 5 columns 36 advertisements appear as an introduction to a 5 page presentation of a new food and drug law.

"Know Your Health Department" is a series in *Baltimore Health News*, Baltimore Health Dept., Md. Sketches of staff members, with portraits.

"Public Instruction—One of Today's Big Jobs in Syphilis Control." *Health News*, State Dept. of Health,

Albany. Feb. 14, 1938. A review of progress in terms of New York State.

Six pages of pictures and text were reproduced in *Everybody's Health*, 11 W. Summit Ave., St. Paul, Minn. Jan., 1938. From *Life*, *Look*, and *Literary Digest*, 2 pages each, with a double page spread of Minnesota pictures.

"Timely Articles in Recent Publications," and "Book and Pamphlet Notices" are headings in *Ohio Public Health*, Ohio P.H.A., 1575 Neill Ave., Columbus.

"Your Body and Health," a series of health lectures in Providence, is described in *Health Review*, Rhode Island State Dept. of Health, Providence. Jan. 1, 1938.

DATES AHEAD

Early Diagnosis Campaign is now on, an opportunity for many welfare and health agencies to coöperate with the tuberculosis groups.

This issue will be out in National Negro Health Week. For reports watch for *National Negro Health News*, U. S. Public Health Service, Washington, D. C. *Free*.

A mimeographed health sermon, distributed for use in N. N. Health Week, will be useful where the Week is celebrated locally at a later date. *Free* from U. S. Public Health Service.

U. S. Children's Bureau was established 26 years ago. Worth talking about.

And the start of National Child Labor Committee 34 years ago is worth a word of thanks.

St. George slew the dragon on April 25.

Again, Moving Day, May 1, is a time for certain health suggestions.

And May Day will again be Child Health Day in many communities.

Mother's Day, May 8, will be officially celebrated locally within the week before or week after, by American Legion Posts. Much maternal care

material will appear in newspapers and magazines. For plans and data write to Maternity Center Assn., 1 E. 57th St., New York, N. Y.

National Hospital Day and Birthday of Florence Nightingale come May 12.

June makes the 57th year of Red Cross history in the United States.

MAGAZINE ARTICLES

"Are You Afraid of Syphilis?" by R. E. Lindenberg. *Survey Monthly*, 112 E. 19th St., New York, N. Y. Feb., 1938. 30 cents. Some employment and other back-firing from publicity. In same issue: "Women and Children Last," by Beulah Amidon. Based on the recent Children's Bureau Conference.

"Cold Comfort," by J. D. Ratcliff. *Collier's*. Feb., 26, 1938. "A sneeze from a sick ferret proved the answer to a researcher's prayer."

"A Health Program for Rural America," an interview with Dr. Thomas Parran by Carroll P. Streeter. *Farmer's Wife Magazine*, St. Paul, Minn. March, 1938. 5 cents. 3 cents each for 10 or more.

"Insanity and Insulin," by C. Charles Burlingame. Hope in the use of insulin. . . . "Birth Control and Prosperity," by E. H. Clarke. Economic significance of lowering the birth rate. *Forum*, 570 Lexington Ave., New York, N. Y. Feb., 1938. 35 cents.

"Killed in the Kitchen," by Dr. Louis I. Dublin. *This Week*, the newspaper Sunday magazine distributed in many cities. Nov., 14, 1937.

"The Life of a Medical Student" is a 6 page spread, arranged by Dr. Morris Fishbein from pictures taken in 5 Chicago medical schools. *Look*, Des Moines, Ia. March 15, 1938. 10 cents.

"One Out of Ten Has It," by D. Beres. *New Republic*, 40 E. 49th St.,

New York, N. Y. Sept. 25, 1937. 2 col. review of books by Parran and Becker. A sample of magazine space gained through book reviews.

"Our Arthritis," by Dr. Logan Clendening. *Saturday Evening Post*. Feb. 12, 1938.

A 2 page advertisement of *Ladies' Home Journal* in *Saturday Evening Post* for Jan. 22, 1938, itself was an effective piece of health education.

In color; head and bust of a young woman at left; "Yes! I will take a Wassermann Test" across top of the two pages; right page in text, with "This New Attitude Affects Your Own Business" in a panel.

"When We Choose Health Insurance," by Dr. D. W. Orr, and Jean W. Orr. *Survey Graphic*, 112 E. 19th St., New York, N. Y. March, 1938. 30 cents. Consideration of questions growing out of the series of papers reporting on the actual working of British health insurance.

RADIO

Chicago Board of Health is broadcasting some aspect of syphilis Wednesday and Saturday, 1:35 P.M., over Station WAAF.

Manitoba Dept. of Health and Public Welfare, Winnipeg, started "The Health Reporter" in Oct., to run through May 27, over Stations CJRC and CJGX, Thursday, 8:05 P.M., to 8:15 P.M.

A health reporter will give a summary of the week's news concerning new health ideas and events, as a means of keeping listeners in touch with health matters of current interest.

Manitoba's "Health Review" comes over Stations CKY and CKX every Wednesday, 4:45 to 5:00 P.M. From March 30 to May 11 will run

"The Health Detective in Science," a series of 7 talks to relate how science aids in safeguarding and promoting health and welfare. Three talks on venereal diseases will be included in the spring and summer

program as a continuation of the series given last season.

"Motor vision in safe driving" and "Sight saving." Radio talks in *Sight-Saving Review*, 50 W. 50th St., New York, N. Y. Sept., 1937. 50 cents.

"Our Daily Bread" is a broadcast interview by Dr. James A. Tobey. Copies for use from American Institute of Baking, 9 Rockefeller Plaza, New York, N. Y. Free.

Hartford Tuberculosis and Public Health Society, 488 Main St., broadcasts weekly over WDRC and WTIC.

Baltimore City Health Dept. and Medical and Chirurgical Faculty of Maryland:

Pasteurized pastries prevent disease. . . . All fireworks are dangerous. . . . Helpful use of summer leisure. . . . Keeping well eyes well. . . . Tick-bite fever. . . . Save a life! (from drowning). . . . Death may lurk in the paint can (danger to little children of lead in paint). . . . Water, crystal clear and safe. . . . Banish the common food containers.

Quoted from a radio talk: ". . . to develop immunity for the *oral administration* of . . ." (Our italics.)

The annual *World-Telegram* poll of radio editors asked for opinions as to NBC's refusal to allow General Hugh Johnson to broadcast on venereal diseases. The majority of the editors were against the censorship.

"Catalog of Electrical Transcriptions of Radio Health Plays." New York State Dept. of Health, Albany. Revised. Lists 117 records; plays only; no opening or closing announcements; no mention of New York State Dept. of Health; running about 10 minutes; suggested opening and closing announcements supplied with the records. There are 23 additional records for use in New York State only, because they include the opening and closing announcements.

"Educational Broadcasting Needs Improvement," by Hopkins and McCarthy is a helpful resumé of selected

points made in the Second National Conference on Educational Broadcasting, Chicago, Nov. 29-Dec. 1, 1937. In *Bulletin*, National Tuberculosis Assn., 50 W. 50th St., New York, N. Y. Feb., 1938. Copies may be found in any tuberculosis association office.

A review of Second National Conference on Educational Broadcasting is in *Education by Radio*, 1 Madison Ave., New York, N. Y. Jan., 1938. Free.

Wisconsin Anti-Tuberculosis Assn. conducted its third annual High School Health Radio Contest, closing Dec. 23, 1937, in coöperation with *Milwaukee Journal* station.

We have seen only a few of the expanding collection of books on broadcasting. Yet we doubt that anywhere else will the health broadcaster get as much for so small an investment as in a copy of "Handbook for Amateur Broadcasters," by Pauline Gibson. Scholastic Publications, Chamber of Commerce Bldg., Pittsburgh, Pa. 60 pp. Many illustrations. 50 cents. The Handbook is addressed primarily to high school, college, and little theatre groups. It gives many helpful glimpses behind the scenes in actual broadcasting, together with much of the sort of information and suggestion needed by amateur writers, actors, and producers. It will be helpful in mock broadcasting on the stage or in the classroom; in broadcasting over school loud speaker systems; and in actual station broadcasting.

SCHOOLS AND CHILDREN

Although we announced the discontinuance of School Education Service (partial successor to American Child Health Assn.) it may be well to reprint this request sent out last September:

The School Health Education Service, conducted since 1935 under the auspices of the Joint Committee on Health Problems in Education, has been discontinued.

Will you please take this name from your mailing list and delete any reference to services formerly obtainable from this source from your reference lists and bibliographies.

Readers, please note that incorrect addresses and out of date references are amazingly long lived. Better check reference lists and address files.

"Alcohol in Youth's World," by W. R. Breg. *Journal*, N. E. A., 1201 16th St., N.W., Washington, D. C. Oct., 1937. 25 cents. Something about the problem; something about Allied Youth, at the above address, which seeks to serve the schools in meeting the problem.

An interesting example of interpretation comes from Dr. R. K. Galloway, director, school health service, Public Schools, Nashville, Tenn. Dr. Galloway writes:

The Nashville Council of Parent-Teachers' Associations is publishing this year a bulletin each month pertaining to the city school system, that they are distributing to their respective organizations, and other local interested citizens. The subject of the September number was the "History of Nashville Schools," October's bulletin was on the "Physical Condition of the School Buildings," and the November issue was edited by us on the "School Health Service."

Probably the mimeographing and binding of the Nashville pamphlet was done by students. A sub-heading, or two of them, on every page would have aided the reader.

"Dental Health Education: Can School Children Get It?" This question is asked and answered in Feb., 1938, issue of *Bulletin*, Mich. School Health Assn., Ann Arbor, Mich., even though the address is not given in the *Bulletin*.

"The Problem Solving Approach in Health Teaching" comes from Michigan Joint Committee on Health Education, Haven Hall, Ann Arbor. 25 cents. The Foreword says:

Various methods are used in the schools to help children achieve "healthy living."

Some of these methods are more closely related to the needs of boys and girls than others and seem more effective in changing their actual behavior. This bulletin reports a type of activity in which pupils and teachers coöperate in the discovery and handling of the actual health problems of home, school and community.

The American Dental Assn., 212 E. Superior St., Chicago, Ill., is conducting a national dental health poster contest. Local and state contests lead up to the national, including display of posters at the annual meeting of A.D.A. in St. Louis next October. Write the association for details.

"Health of School Children Far and Near," by Sally Lucas Jean, *Public Health Nursing*, New York, N. Y., Dec., 1937. *Junior Red Cross Journal*, Washington, D. C., is doing a fine job on social problems in high schools. "What About the Home Town?" by Leonard W. Mayo, in the Jan., 1938, issue takes up "Haunted Houses." Housing is presented as a story of high school students who study the subject, and try to do something about it.

Probably the biggest circulation among health periodicals is that of *The Health Broadcaster*, a "monthly health newspaper published for pupils, parents, and teachers" by Department of Health Education of Board of Education, 157 E. 67th St., New York, N. Y. In the school year once a month 1,400,000 copies are distributed of this 4 page, 8 by 10 inch. publication.

"The Tuberculin Test in the Schools of San Francisco," by Geiger, Owen and Barret. Dept. of Public Health, San Francisco, Calif. Reprint. Free.

"Safety and Health of the School Child," by Dr. J. F. Rogers. Office of Education. "A self-survey of school conditions and activities." Questions, with practical annotations. Supt. of Documents, Washington, D. C. 29 pp. 10 cents.

"Setting the Stage for Safety," by

H. J. Stack. *Journal of Health and Physical Education*, 311 Maynard St., Ann Arbor, Mich. Sept., 1937. Why do something in high schools; what health and physical education department may do alone, and in correlation with other teaching departments.

"Sources and Uses of Health Material," by Mary P. Connolly. *Journal of Health and Physical Education*, Ann Arbor, Mich. Dec., 1937. 35 cents. Presented at National Education Assn., June, 1937. Based on secondary school group. Three conclusions are quoted:

"The health education teacher must be a sympathetic leader who will encourage the students to study their own situations and to form ideas of their own wants and needs . . . We may learn about the things which are supposed to be good for us, but if they have no relation to our wants, they never become a vital part of us."

"These suggestions may seem to impose a large amount of preparation on the part of the teacher. And they do. However, the vision of the teacher and her preparation for living will convey more to the student than any amount of formal teaching which she may do. If there are advances in health protection, she should know them, and intrigue the interest of the students. They will want to know about them too, if they are tied to their lives."

"... every backyard contains acres of diamonds in one form or another if we only look for them. The same may be said of materials for health education. They lie all around us, waiting to be picked up and used and made a vital part of some student's life."

"Timely Tips on Scout Protection" runs in many issues of *Scouting*, 2 Park Ave., New York, N. Y. Sample free. Files probably available in most communities. A wide range of practical material for use with boys, girls, and young people.

REPORTING

A group of annual reports have been coming to the editor for 10 to 15 or more years. Among them are several which might well be reprintings of earlier issues with a new date on covers

and title pages. A close examination of text and tables is needed to assure the reader that he really is looking at 1938 data.

The latest issues of these reports look like the earlier ones. The reader is not forced to recognize that progress has been made. The appearance of the report suggests the routine reporting of a routine job. It carries no atmosphere of life and growth. The citizen, or the fellow professional, must seek the evidence of growth in the face of seeming somnolence. However, and here's the rub, probably in many states and cities, type, size, paper, etc., etc., are prescribed by a supervising authority, or are subject to a state printing contract. What can be done in the face of all that?

We have some tentative ideas which can be submitted—if any health agency cares to consider them.

The annual report of New York State Dept. of Health (Albany), volume 1, is a 420 page volume, including 16 pages of index. Even that index does not fully satisfy this reader who would like to see some additional cross-references. For example: we do not find under cancer, slides, photographs, exhibits, transparencies, or public health education any reference to the following quoted paragraphs, 2 of 5 paragraphs under the sub-heading, "Photography," in the report of Division of Cancer:

The photographic department has continued its service to the Institute. For the clinical department we have photographed all patients with visible lesions and supplied lantern slides for the staff for lectures as well as reproductions necessary to illustrate the papers written during the year. A good part of our time has been given to the making and arranging of exhibits. This department has supplied transparencies both for lay and medical meetings during the past year. At the present time we have over 900 transparencies in black and white as well as in color.

Our lantern slide library now numbers

over 3,000 slides and it is becoming so large that the available storage space is very rapidly becoming insufficient. The severe handicap with which we have to deal is the lack of sufficient space to store necessary equipment as well as lantern slides, transparencies, negatives and our records. We hope that room can be procured to overcome this condition.

"Middletown First in Group for Health in Cities of the United States," is the heading of a slip for enclosure to 5,100 subscribers by the Orange County (New York) Telephone Company. The slip explained the 1937 appraisal award. The idea originated with the telephone company.

Released for morning papers Jan. 1, 1938, was a 12 page, legal size, review of the city's health presented by Commissioner John L. Rice to Mayor LaGuardia. For some years now the statistical and reporting machinery of the New York City Dept. of Health has been geared to produce preliminary data of considerable significance for immediate public use at the end of the calendar year. Doubtless copies will be supplied upon request.

Dated September, 1937, is a "summary report" of New York City Dept. of Health, 47 printed pages, covering 1934-1936.

"What the Health Department Nurse Does for You." Bureau of Nursing, Dept. of Health, 125 Worth St., New York, N. Y. *Free*. 15 pp.

A nurse's day; tuberculosis comes to a home; citizens of the future; there is a placard on the door; tomorrow's grown-ups; on the safe side; 35 years of work.

FOR EDUCATION OR REFERENCE

Some of the single publications mentioned here need to be asked for promptly before the edition is exhausted.

"An organization to better the standards and administrative practices of all kinds of public activity in housing for families of low and moderate income."

This is National Association of Housing Officials and others, not housing officials, 850 E. 58th St., Chicago, Ill. Please ask for a descriptive pamphlet.

"Child Labor in the Tiff Mines" (Missouri), by C. E. Gibbons. National Child Labor Committee, 419 4th Ave., New York, N. Y. 30 pp. 25 cents.

"Community Provision for the Serum Treatment of Pneumococcic Pneumonias," by a committee of New York Academy of Medicine, 2 E. 103d St., New York, N. Y. *Free*.

"Disease Conditions of the Mouth and Their Relation to Health." American Dental Assn., 212 E. Superior St., Chicago, Ill. 13 pp. 5 cents. Also, "Dentistry and Public Health." Large page, illustrated, popular. 31 pp. 10 cents.

"Help Yourself to Good Teeth" is an envelope size, 4 page folder emphasizing that proper food plus cleanliness plus dental care equals sound teeth. Dept. of Health, New York, N. Y.

"How to Join the 3 Cents-a-Day-Plan for Hospital Care." Tells what, who, and how. Associated Hospital Service, 370 Lexington Ave., New York, N. Y.

"Many a Germ 'Twixt Cup and Lip" is a 4 page folder, reproducing a cover page of *Readers Digest*, with an abstract of an article from *Survey Graphic*. Copies free from Public Health Committee of Cup and Container Institute, 50 W. 50th St., New York, N. Y.

"The Safety and Sanitary Features of Excellent Rooming Houses" is a 4 page folder distributed by Health Service, University of Illinois, Champaign.

"Bibliography on Public Health and Allied Subjects." This is the 24 page classified list of books issued in the last 5 years. *All titles are dated*. Additions to the previous annual list are

indicated. *Free* from American Public Health Assn.

If you wish to check health education (including physical education and recreation) publications issued by Office of Education, Washington, D. C., consult "List of Publications of Office of Education, 1910-1936." No price is given.

"Literature, Posters and Exhibits for Women's Field Army." American Society for Control of Cancer, 1250 6th Ave., New York, N. Y. *Free* list.

"Pictorial Charts and Maps." A 20 page catalogue of pictorial charts, lantern slides, ready-made symbols. Pictorial Statistics, 142 Lexington Ave., New York, N. Y.

"Publications on Play and Recreation." National Recreation Assn., 315 4th Ave., New York, N. Y. *Free*. Classified list of publications, some of which are free.

"Public Health Service Publications." List of publications issued Jan. to June, 1937. U. S. Public Health Service, Washington, D. C. *Free*.

From Nursing Information Bureau, 50 W. 50th St., New York, N. Y.

"Nursing and the Registered Nurse." 54 pp. 10 cents. . . . "Nursing and How to Prepare for It." 21 pp. 5 cents. . . . "Nursing a Profession for the College Graduate." 17 pp. 5 cents.

National Organization for Public Health Nursing, 50 W. 50th St., New York, N. Y., reprints at 10 cents each:

"A Training Course for Volunteers in the Public Health Nursing Field" . . . "A Program for Staff Education: Infant and Preschool Health" . . . "Vacations and Hours of Work for Public Health Nurses in 1937."

RECOGNITION AND INSTRUCTION

A Council on Public Education, Michael M. Davis, Chairman, is one of the 6 Councils of the American Hospital Association, according to 1937 convention action.

Item 13 in the general purposes of the Chicago Hospital Council:

To plan, organize, and carry out a program intended to inform and educate the public regarding hospitals and the intelligent use of the services which they offer.

In the annual meeting of the New Jersey Tuberculosis League a "health education session" was conducted by William A. Doppler of Health Education Service, National Tuberculosis Assn.

The New England Health Education Assn. has planned three series of section meetings to be held in the fall and winter months; school nurses, full-time teachers, and classroom teachers. Address the Secretary, Katherine Hitchcock, Simmons College, Boston, Mass.

Planning window displays for local health and social agencies Evart G. Routzahn spent an afternoon with agency representatives in Greenwich, Conn.

"Taking the Public With You," by Mayhew Derryberry, U. S. Public Health Service, was on the program of the State Health Conference, Charleston, W. Va., Nov. 9, 1937.

PLANNING PUBLIC EDUCATION

"Health Education in Pennsylvania," by A. M. Dewees. *Bulletin*, National Tuberculosis Assn., 50 W. 50th St., New York, N. Y. June, 1937. "How the State Association organizes its program."

"Publicity in Control of Tuberculosis," by J. M. Bridges. *Bulletin*, National Tuberculosis Assn., 50 W. 50th St., New York, N. Y. Reviews use of newspaper and radio, and emphasizes the publicity material ready at hand in tuberculosis work (applies to other health work?).

There is conflict in your relentless battle against tuberculosis; drama in the work of your clinics and your nurses; consequence in the results that may be expected when your research opens up new possibilities of overcoming disease; prominence in the names of the men and women in your respective communities who have given and continue to

give of their time and effort in this worthy cause; oddity in the facts which your clinics reveal; human interest in its broadest sense in the opportunities to serve those who cannot serve themselves; tragedy in the failures to apply the principles which you have been endeavoring to establish in the minds of America; and the sublime satisfaction of a job well done in the notable accomplishments attributed to your organization.

"Sewage Disposal—Its Effects Upon Public Health," by Drs. Cox and Ehlers. Conditions in certain cities which led to active campaigning by the State. *Municipal Sanitation*, 24 W. 40th St., New York, N. Y., Oct., 1937. 15 cents.

PUPPETS—MARIONETTES

Because of local and nearby interest in puppetry we hope that at Kansas City, next October, we will have a demonstration of the educational use of puppets. And why not some puppet examples in the convention Hobby Show?

If interested in puppets, for education or as a hobby, it will be a delight to read and look through Paul McPharlin's "Puppets in America: 1739 to Today." The record really starts before the days of Columbus, with several illustrations of puppet types used by American Indians before the days of white men. A readable review of how puppets came west to America, how they flourished and waned, and flourished again, precedes an intimate personal story of the first American puppetry conference. More than 180 hand puppets, marionettes, rod and shadow puppets are pictured, thus illustrating many types of characters and of puppetry presentation. Published by Paul McPharlin, Birmingham, Mich. \$2.00.

"Making Marionettes," by E. F. Ackley. *American Junior Red Cross Notes*, Washington, D. C. Oct., 1937. 10 cents. Simple directions for home or school.

"Marionettes Become Health Conscious," by Edith S. Countryman, R.N. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Aug., 1937. 35 cents. Includes "Infanticipating at the Kelly's" in 3 scenes.

"Marionettes in Parent Education," by J. K. Francis. *Journal of Home Economics*, Mills Bldg., Washington, D. C. Nov., 1937. 30 cents.

Marionettes, the dolls of the adult, can be used successfully to illustrate parent education, with a dialogue written to emphasize interesting points.

The making of marionettes is a hobby requiring skill and patience and has provided an artistic outlet for many persons. There are many helpful books available on the technic of making them. The shaping and balancing of the doll's body appeal to the mechanically minded. Dolls made with wood bodies and jointed with metal screw eyes are sturdy and pliable. Leather strips are often substituted for screw eyes and make a more graceful doll. The completion of a marionette gives one the sense of having created a real actor.

Some puppets are marionettes, as explained in "Puppets in America," by Paul McPharlin:

In modern usage, the name *puppet* is given all theatrical figures animated under human control. Some puppets, worked from above by strings, are called marionettes . . . Hand-puppets, with hollow bodies into which the fingers and wrist are thrust to give movement, run second in popularity. Shadow-figures, black or colored, have great effect, and are not so often seen as they might be. A few producers are experimenting with rod-puppets. Cardboard figures worked with wires from the wings of a toy stage are occasionally revived for living-room entertainment. There are 7 puppet types and their variants, each of which is fascinating in its own way.

With any kind of interest in puppetry you will be interested in "Puppetry Bulletin: 1937-1938." Where to get supplies and equipment; the new books and pamphlets; classification of puppets. Paul McPharlin, Birmingham, Mich. 24 pages. 3 cents.

BOOKS AND REPORTS

Books of Special Interest to Public Health Workers

MAZYCK P. RAVENEL, M.D.

OUR annual review of books on public health has been favorably received for several years so that it has seemed worth while to go over those published in 1937 and a few in the early months of 1938, and call them once more to the attention of public health workers, physicians, and nurses, and, in fact, to all who are interested in preventive medicine and public health. As in the past, our selections have been based chiefly on books reviewed in this *Journal*. Among others, however, which have been read through the year and from which selections have been made are the *British Medical Journal*, *The Lancet*, and the *Journal of the American Medical Association*. We trust that the present review will meet with the approval of our readers and give some helpful suggestions.

NUTRITION

We have elsewhere pointed out that in England the two great public health movements which have been attracting attention for several years past are housing and nutrition. That housing is attracting attention in this country is shown by the fact that at our Annual Meeting we had a symposium on the Hygiene of Housing; yet few books have come in to us during the current year on either housing or nutrition. It is true that there have been a number of new editions and compilations on nutrition, but no outstanding works have come to our attention. Among these in view of its originality

and its practical bearing, there should be mentioned *Dr. Nash's Cookery Book*, by Elwin H. T. Nash, Simpkin, Marshall, Ltd., an extensive study on providing nutritious foods and preparations at low cost. It is very highly spoken of in England and has had favorable reviews in this country. *Man, Bread and Destiny*, C. C. and S. M. Furnas, Reynal & Hitchcock, is a discussion of the development of civilized man interpreted through his food intake, a fascinating study of nutrition adapted to the layman. Among the notable new editions are *Chemistry of Food and Nutrition*, by Henry C. Sherman, 5th edition, Macmillan, which is an indispensable text, *Vitamins—In Theory and Practice*, by Leslie J. Harris, 2nd edition, Macmillan, presents with a minimum of academic uncertainty a summary of knowledge in this field. It is unexpectedly complete and has an up-to-date wealth of detail. *Dietetics Simplified*, by L. Jean Bogert and Mame T. Porter, Macmillan, is intended primarily for students in home economics. It contains information for the public also, and is authentic, complete, and understandable. *A Laboratory Handbook for Dietetics*, by Mary Swartz Rose, 4th edition, Macmillan, has for many years been a standard textbook for college laboratory classes in dietetics and an invaluable source of reference material for all those concerned with practical problems in dietetics. Much new information is given in this edi-

tion. *Food Technology*, by Samuel C. Prescott and Bernard E. Proctor, McGraw-Hill, is an impressive book designed to aid in training the scientific personnel now required in food industry. Of distinct value to sanitarians and all concerned in the production or control of foods. *The Foundations of Nutrition*, by Mary Swartz Rose, 3rd edition: This text appears in a new format, very attractive. It has been brought up to the minute, will maintain its place as a standard for teaching and reference.

NURSING

The past year has been notable in that the 25th anniversary of the National Organization for Public Health Nursing was celebrated. There have been papers of various kinds, but only one book which we have seen. *Nursing as a Profession*, by Esther Lucile Brown, Russell Sage Foundation, is a reliable and up-to-date source of information for all interested in nursing, giving an insight into the aims, activities, and problems of the nursing profession. *School Nursing: A Contribution to Health Education*, by Mary Ella Chayer, 2nd edition, Putnam, is revised and enlarged, with a chapter on Rural School Nursing, and is practical in every chapter.

HYGIENE AND INDUSTRIAL HYGIENE

Under the general heading of hygiene, industrial hygiene is still demanding much attention, as new chemicals, many of them known to be as possibly injurious to workers are coming more and more into use. The revival of industry in 1937 brought some of these things to the fore. No great work has appeared during the year. Worthy of mention, however, are *Facts and Frauds in Woman's Hygiene*, by Rachel Lynn Palmer and Sarah K. Greenberg, Vanguard, which is especially valuable for lay women. *Modern Principles of Ven-*

tilation and Heating, by T. Bedford, H. K. Lewis & Co., which consists of three lectures under the Heath Clark Bequest at the London School of Hygiene and Tropical Medicine. By an outstanding authority, this work will have a wide reception in this country. *Second Symposium on Silicosis*, by B. E. Bekuechle, Editor, Employers Mutuals, is indispensable to all those who are interested in silicosis. *Personal Hygiene*, by C. E. Turner, Mosby, is a practical text written in interesting style. *Handbook of Hygiene*, by Joseph W. Bigger, Wood, is a 5th edition. The market is flooded with books on hygiene. This is an especially good one, concise and adapted to general use. *A Synopsis of Hygiene*, by W. W. Jameson and G. S. Parkinson, J. A. Churchill, Ltd., is a standard work in its 5th edition.

HEALTH EDUCATION

Health education has been well represented during the year as it generally is. The outstanding books seem to be *Creative Re-education*, by Frederick Paterson, Putnam, which is an "inspiration to all who are attempting to solve the problems of human needs." *The Doctor and the Public*, James Peter Warbasse, Hoeber, is "A timely book, yet not one that will soon be out of date." *A Health Education Workbook*, by Kathleen Wilkinson Wootten, Barnes, is designed for teachers, parents, nurses, and social workers and is an excellent practical text of great value for teachers, school officials, and health workers. *Tuberculosis Education: A Guide for Professional and Lay Workers*, by Elma Rood, Rural School Press, is rich in suggestions for health officers, public health nurses, school administrators, teachers, and community workers. *Adventures in Living Series*, by Thomas D. Wood, Anette M. Phelan, Marion O. Lerrigo, Nina B. Lamkin, and Thurman B.

Rice, Nelson—*Now We Are Growing, Many Ways of Living, Keeping Fit, Blazing the Trail, How We Live*—is an interesting series giving the latest developments in preventive medicine, and at the end of each chapter ingenious suggestions are made for vitalizing health teaching. *Man in a Chemical World*, by A. Cressy Morrison, Scribner, is both cultural and practical. It commemorates the 300th anniversary of the birth of the chemical industry in the United States and is a remarkable and useful story. *The Measurement of Outcomes of Physical Education for College Women*, by Elizabeth Graybeal, University of Minnesota Press, is important as an attempt to evaluate the great efforts now being made in all educational institutions on physical education.

BACTERIOLOGY, PARASITOLOGY AND PATHOLOGY

Perhaps the most notable book under this grouping is *Clinical Parasitology*, by Charles Franklin Craig and Ernest Carroll Faust, Lea & Febiger. It is a new textbook by leading American authorities on tropical medicine and parasitology and is undoubtedly the standard textbook in its field. *Malaria in Europe*, by L. W. Hackett, Oxford University Press, is a valuable contribution to the book-shelf of malariologists, physicians, public health workers, and laymen interested in control of this disease. *Handbook of Microscopical Technique*, by C. E. McClung, 2nd edition, Hoeber, contains many improvements over the first edition and is of great value as a book of reference. *Manual of Public Health Laboratory Practice*, by J. R. Currie and Contributors, Wood, is an excellent book for graduates, but is written for those working under English conditions. *Atlas of Hematology*, by Edwin E. Osgood and Clarice M. Ashworth, W. Stacey, Inc., concerns public

health only in the differential diagnosis of some of the anemias, though is so outstanding as to call for mention here. There is no better work on the subject. *Disinfection and Sterilization*, by Ernest C. McCulloch, Lea & Febiger, is a fine piece of work which will be appreciated by those who find the literature on the subject overwhelming and who are looking for definite knowledge. *Phenomenon of Local Tissue Reactivity and Its Immunological, Pathological and Clinical Significance*, by Gregory Schwartzman, Hoeber, is especially useful to immunologists and clinicians in assembling in one volume the mass of scattered observations on the Schwartzman phenomenon. It constitutes a fine memorial to the high ideals of the author. *Pathology (Clio Medica)*, by E. B. Krumbhaar, Hoeber, is a remarkable, concise and accurate treatment of this important branch of medicine. *Practical Bacteriology, Haematology and Animal Parasitology*, by E. R. Stitt, 9th edition, Blakiston. This has always been the leading book in its line in the English language, if not in any language, and it is hard to speak too highly of it.

SYPHILIS

Because of the campaign which is being waged against syphilis, it is felt that a separate heading should be devoted to it. A notable book is *Shadow on the Land—"Syphilis,"* by Thomas Parran, Reynal & Hitchcock. It bears evidence of the interest in this scourge of mankind awakened in this country by the Surgeon General of the Public Health Service. The book brings out forcibly the important place in our public health program held by syphilis, and points the pathway to control. Two other books on syphilis have appeared. *Syphilis Sive Morbus Humanus: A Rationalization of Yaws So-Called*, by Charles S. Butler, Science Press Printing Co., is largely devoted

to a discussion of the origin of syphilis. *Who Gave the World Syphilis? The Haitian Myth*, by Richmond C. Holcomb, Froben Press, is a critical study of the controversy over the geographical origin of syphilis, well worth reading from every point of view. These books should be read together. There is also *Laboratory Diagnosis of Syphilis*, by Harry Eagle, Foreword by J. Earle Moore, Mosby, which deserves mention.

CANCER

There have been many articles on cancer and everyone knows of the intensive studies being carried out on this disease all over the world. A most useful book is *Some Fundamental Aspects of the Cancer Problem*, edited by Henry B. Ward, Science Press. It is a valuable study giving a good cross-section of cancer research at present.

MATERNAL CARE

The Principles of Antepartum, Intrapartum and Postpartum Care for the Practitioner of Obstetrics, by F. L. Adair, Editor, University of Chicago Press. Though written for the practitioner, this concise booklet will be useful to public health nurses, physicians generally as well as all others whose duties bring them into contact with prospective mothers.

CHILD CARE

Child care in its various aspects has been the subject of many articles, but not many books have come to our notice. *Guide Book for Mothers*, by Allan Roy Dafoe, Julian Messner, Inc., is written in delightful style by the famous doctor who attended at the birth of the Dionne quintuplets and guided their early days to health. *Child Care and Training*, by Marion L. Faegre and John E. Anderson, 4th edition, University of Minnesota Press. The demand for a fourth edition shows the value of this work. The authors

have preserved a judicious balance between the physical, mental, emotional and social factors.

VITAL STATISTICS

Only one book of importance on this subject has come to us, *Statistical Methods in Biology, Medicine, and Psychology*, by C. B. Davenport and Merle P. Ekas, 4th edition, is "recommended to all who require data on statistical methods of the type developed by the Pearsonian school."

HISTORY

Some unusually interesting books on history have appeared. A notable book is that by Sir Arthur Newsholme, *The Last Thirty Years in Public Health: Recollections and Reflections on My Official and Post-Official Life*, George Allen & Unwin, Ltd., which is packed with observations on the history, evolution, and administrative solution of public health problems. Another unusual book is *The Mentally Ill in America: A history of their care and treatment from Colonial Times*, by Albert Deutsch, Doubleday, Doran. This is particularly valuable in view of the increasing recognition of the importance of mental hygiene in our health program. A scholarly review long needed is here supplied. An interesting book of especial value to Americans is *History of County Health Organizations in the United States, 1908-1933*, by John A. Ferrell and Pauline A. Meade, *Public Health Bulletin* 222, Public Health Service, which is a valuable source book for public health administrators and public health students in the United States.

Two unusually interesting autobiographies have appeared. *A Woman Surgeon*, by Rosalie Slaughter Morton, Stokes, is an interesting account of a useful and adventurous life. *Life and Death: The Autobiography of a Surgeon*, by Andrea Majocchi, Knight

Publications, is an unusually fascinating book with reflections on medicine, human nature, religion, superstitions, etc., through all of which the author has maintained his faith in this life and the hereafter. A book which has been reviewed most favorably is *The Mind of Man: The Story of Man's Conquest of Mental Illness*, by Walter Bromberg, Harper, which is highly recommended for historical content, and physicians generally are advised to read it.

GENERAL

It is difficult to put some books in a hard and fast group. A notable and unusual book is *American Medicine: Expert Testimony Out of Court*, by leading doctors and surgeons, the American Foundation, 2 volumes. Few books have led to more discussion of fundamentals than these volumes. We have published a review and a long editorial on the matters brought out, and it remains only to call attention again to the work, which deserves study. *The Environment and Its Effect Upon Man*, by the Harvard School of Public Health, is an effort to correlate a few of the many aspects of this subject and consists of some 19 papers by experts in their respective fields and representing our latest ideas. *Trauma and Disease*, edited by Leopold Brahdly and Samuel Kahn, Lea and Febiger, is an extension of the usual idea of public health which has been needed for many years, and is deserving of a warm welcome. *The Traffic in Health*, by Charles Solomon, Navarre Publishing Company, Inc., is an unusually good discussion of the patent medicine question, covering habit formers, proprietary medicines, cosmetics, etc., concluding with sound advice and a good bibliography. In many ways the most notable work on this general subject. We have put under this general head-

ing two books which might have a heading of their own: *The Psychology of Abnormal People*, by John J. B. Morgan, 3rd edition, Longmans-Green, is a second edition brought up to date of a book that is a leader in its field. *Textbook of Psychiatry*, by Arthur P. Noyes, 2nd edition, Macmillan, is a thorough revision, giving in synoptic form the broad field of general psychology and paying special attention to the field of psychiatric nursing. Under this general heading we are putting also an unusual book, especially valuable, *Principles and Practice of Public Health Dentistry*, by J. A. Salzmann, with chapters by Dr. Struthers, and Dr. McCall, Stratford. This is a book which covers a new field, of particular value in view of the increasing interest in oral hygiene by the medical profession. Deserves a wide circulation among health officers, public health workers, and doctors.

The year has seen also a new edition of *A Practical Medical Dictionary*, Thomas Lathrop Stedman, 13th edition, which celebrates the 25th anniversary of the work, and is excellent from every point of view.

Public Medical Services: A Survey of Tax-supported Medical Care in the United States, by Michael M. Davis, University of Chicago Press, is a useful and compact statement. *First Aid Textbook*, American Red Cross, Blakiston, Revised edition. "Never has the need for first aid been greater than at present. . . ." *Everyday First Aid*, by Walter Frank Cobb, Appleton-Century, is a manual for those who would be prepared—prevention, though the importance of first aid treatment is also well handled. *The Pneumonokonioses (Silicosis) Literature and Laws of 1934*, Book III, by G. G. Davis, E. M. Salmonsens, and J. L. Earlywine, Chicago Medical Press, is important for specialists and libraries.

Preview of Books for Public Health Workers

AT the invitation of the Book Service, publishers have submitted descriptions of books which will be published during 1938. Public health workers will be interested in knowing of these books in preparation. The evaluation in every case is the publisher's own.

Adventures in Respiration

By Yandell Henderson, *Department of Applied Physiology, Yale University.* William Wood & Company. Price probably \$3.00. (In preparation.)

Goes well into the physiology of respiration and deals comprehensively with all phases of asphyxia under various conditions. A book which applies the most recent knowledge of physiology to problems both ancient and very modern, including mining, aviation, automobiles and war.

An Appraisal Form for Local Health Work

By Committee on Administrative Practice, *American Public Health Association.* (In preparation.)

This combines the separate rural and city "measuring rods" for community health previously published. In the first part, a series of simple tabulations provides a means of collecting essential statistics of health conditions as seen against a background of community characteristics. In the second part, public health activities are recorded and appraised. In the third part a list of indices rounds out the picture of community health by briefly summarizing conditions of living, health status of the population and organized health services.

Brief History of Nursing

By Minnie Goodnow, R.N. W. B. Saunders Company.

This book (not to be confused with the author's *Outline of Nursing History*) is an entirely new presentation planned for students in schools where only a limited course is given in nursing history. Each chapter is presented as a unit in order to permit rearrangement or omission as the teacher may elect. Simplified Review Questions are given at the end of the book.

Essentials of Pathology

By Lawrence W. Smith and Edwin S. Gault. D. Appleton-Century Company.

Presents details of pathology necessary for understanding the nature of organic disease. These directly refer to photographs and photomicrographs of diseased tissues. Case records are combined.

Student learns to coördinate his theoretical knowledge with actual clinical problems.

Exercise and Like It

By Dudley B. Reed, *Whittlesey House Health Series.* McGraw-Hill.

A vigorously written, discursive, infectious book on the value of exercises and sports and how to undertake them. Includes chapters on the physiology needed to explain the uses of exercises, also on choosing a recreation, and "when and how much."

Fifty Years a Country Doctor

By William N. Macartney, M.D. E. P. Dutton & Company. \$3.50. (March 10.)

A wise, bluff old medicine man who is ac-

customed to speaking his mind writes a remarkable account of a life-time of work in northern New York in a community comprised of Indians on a reservation, French Canadian habitants, farmers, and other small-town folk.

Food Control: Public Health Aspects

By James H. Shrader, Ph.D., D.P.H., Formerly Director of Scaltest System Laboratories. William Wood & Company. (In preparation.)

A comprehensive work on methods used in food production and control to safeguard public health. Covers methods of processing, microbiological and chemical methods of food analysis used in control of methods of preparation and in inspection by public health officials. Supplies a long-felt need for a comprehensive reference and text on this subject. Suitable for text in schools of public health, for commercial and public health laboratories, for food inspectors.

Fundamentals of Internal Medicine

By Wallace M. Yater. D. Appleton-Century Company.

Concise descriptions of internal diseases coördinated with the underlying pathology and the altered physiology giving the student sufficient material for understanding the fundamental basis of the symptoms and, therefore, a rational background for diagnosis.

This book presents the minimum amount of knowledge the practitioner and student must have at his command to diagnose and treat disease rationally.

Handbook of Social Hygiene

By W. Bayard Long, M.D., and Jacob A. Goldberg, Ph.D. Lea & Febiger. \$4.00.

Produced in contributions by 17 recognized authorities, including besides famous specialists, a hospital director, a director of nursing, and sev-

eral executive officers of public health associations. It is not only a book for the physician but for the public health worker, the social worker, nurses, and others enlisted in the current campaign for social hygiene. This book furnishes exact and scientific knowledge and tells them everything that they need to know.

Health and a Day

By Lord Horder, K.C.V.O., M.D., B.Sc., F.R.C.P. G. P. Putnam's Sons. 213 pp. \$2.50.

Lord Horder writes understandingly of the strain of modern civilization; of the doctor as humanist; of the doctor and public happiness; of old diseases and new; of the duty of the physician to look at his patient as a personality—a complete entity—and not as a mere bundle of physiological and pathological processes.

How to Live

By Irving Fisher, LL.D., and Haven Emerson, M.D. Funk & Wagnalls Company. 20th edition completely revised and rewritten. \$2.00.

Since its publication in 1915, *How to Live* has had a circulation of almost half a million copies. It is the official handbook of the Life Extension Institute, and a textbook in many colleges and schools.

It is written in simple, non-technical language for the general public, giving the findings of the foremost authorities on how to live healthfully in relation to food, drink, clothing, housing, exercise, work, play, rest, sleep, and other related aspects of human life.

I Swear by Apollo (A Life of Medical Adventure)

By William E. Aughinbaugh, M.D. Farrar & Rinehart, Inc. \$3.00. (April.)

From boyhood in a small Virginia village after the Civil War and medical student days in Washington, up through

the years of disasters, plagues, floods, panics, to the present day of specialization and knowledge, Dr. Aughinbaugh tells his life story. His work led him to the farthest parts of the world. He was among the first to arrive at the scene of the annihilation of St. Pierre by the eruption of Mt. Pelee—he fought plague in the Red Sea on a pilgrim packed ship, and he studied the ravages of leprosy from Venezuela to China.

Medical Writing: Its Art and Technic

By Morris Fishbein, M.D. American Medical Association. (1938.)

This book represents the gradual evolution of the pamphlets entitled, "Suggestions to Medical Authors," long published by the American Medical Association Press. The various chapters concern the preparation of the manuscript, the technic of medical writing, the development of charts, tables and illustrations, the proper use of words, the selection of a title, the writing of a case report, and many similar topics.

Medical Information for Social Workers

Edited by William M. Champion, M.D., School of Applied Social Sciences, Western Reserve University, Cleveland. William Wood & Company. About 400 pages. Price, about \$3.50. (In preparation.)

A concise book of medical information for public health and all social workers who must possess some understanding of medical matters. Based on a course of lectures given at Western Reserve University, it has been extended and written in collaboration with many leaders in the field. Discusses rather fully diseases with social significance such as tuberculosis, and other diseases more briefly.

Mental Hygiene for Nurses

By Elizabeth Lee Vincent of the Merrill-Palmer School. W. B. Saunders Company.

In this new text the author explains the meaning of mental health and its virtues in relation to nursing practice. She applies the principles of mental hygiene to the personal adjustments of the student, to methods of study and to the nursing care of patients.

Pneumonia and Serum Therapy

By Frederick T. Lord, M.D., and Roderick Hefron, M.D. The Commonwealth Fund. \$1.00. (March.)

This is a completely revised and enlarged edition of *Lobar Pneumonia and Serum Therapy* published in 1936. The 1938 edition contains important new information on dosage and results for Types I, II, V, VII, VIII, and XIV, discusses the use of rabbit serum, sets forth in detail the organization of a pneumonia control program, and brings up to date essential information pertaining to serum therapy of pneumococcus pneumonia.

Pneumonia, With Special Reference to Pneumococcus Lobar Pneumonia

By Roderick Hefron, M.D. The Commonwealth Fund. (In preparation.)

This is an outgrowth of the Pneumonia Study and Service conducted by the Massachusetts Department of Public Health. It is an authenticated account of pneumonia, including the causative organisms, epidemiology, immunity, pathogenesis, measures for prevention, course of the disease, complications and their treatment, diagnosis, prognosis, and treatment.

Psychology Applied to Nursing

By Professor Lawrence A. Merrill of the Massachusetts State Teachers College, and Florence C. Kempf, R.N.,

Assistant Principal and Instructor in Psychology at Massachusetts General Hospital Training School for Nurses. W. B. Saunders Company.

This gives to students a complete presentation of the psychological principles which bear on nursing adjustment. The mental hygiene point of view is maintained throughout. The book incorporates the suggestions included in the Curriculum Guide and is aimed at teaching the student to understand herself, and the personalities of others, especially of her patients.

The Adolescent

By Ada Hart Arlitt, Professor and Head of Department of Child Care and Training, School of Household Administration and Graduate School of Arts and Sciences, University of Cincinnati. McGraw-Hill.

Dr. Arlitt gives the modern concise and readable advice on discipline, emotional control, character training, and planning the day for the older child.

The Care of the Infant and the Young Child

By Harry Lowenburg, Sr., M.D., Attending Pediatrician to Mt. Sinai Hospital, Philadelphia General Hospital and to the Skin and Cancer Hospital. With the assistance of John C. Williams, M.D., Assistant Pediatrician to the Germantown Hospital, Philadelphia. Whittlesey House Health Series. McGraw-Hill.

The Devil's Candle

By Ruth De Forest Lamb, author of American Chamber of Horrors, and Chief Educational Officer of the U. S. Food and Drug Administration. Farrar & Rinehart, Inc. \$2.50. (June.)

A constructive and informative book on both the history and the current methods in the protection of the public in the matter of the regulation of foods and drugs.

The Etiology of Trachoma

By Louis A. Julianelle, Ph.D. The Commonwealth Fund. (In preparation.)

Dr. Julianelle reviews the various studies of the etiology of trachoma and correlates with them the findings of the Trachoma Commission established at Washington University several years ago. Some of the observations made at this laboratory have been reported in medical journals, but in this monography they are brought together for the first time and related to existing literature on the subject.

The Truth About Childbirth

By Anthony M. Ludovici. E. P. Dutton & Company. \$2.50. (April.)

The author advances the daring claim that normal childbirth should not be merely painless and uneventful, but actually a fairly safe and pleasurable function. He describes in detail and with scientific documentation the vicious life-habits, the mistaken policies, which today make normal childbirth an impossibility.

Water Supply and Sewerage

By E. W. Steel, Professor of Municipal and Sanitary Engineering, Agricultural and Mechanical College of Texas. McGraw-Hill.

An authoritative, up-to-date treatment combining the subject of water supply, water purification, sewerage and sewage disposal.

Ways to Community Health Education

By Ira V. Hiscock, with the assistance of Mary P. Connolly, Marjorie Delavan, Raymond S. Patterson, Ph.D., and William H. F. Warthen, M.D. The Commonwealth Fund. (In preparation.)

Technics and devices for community health education which have been found practicable by various health de-

partments and voluntary health agencies. The first section considers the methods and vehicles of education in detail with the proper field use of each, while the second section sets forth how these may be correlated to provide an effective health education program for a particular field. Technics to inform specific groups of personal and public health matters and to build public opinion in favor of health services are considered. The book is profusely illustrated.

National Health Survey: Preliminary Reports—*Washington: National Institute of Health, and U. S. Public Health Service, 1937.*

These bulletins are the first of a series of preliminary reports on the results of a nation-wide survey of the extent of illness and the receipt of medical care in relation to a variety of social and economic factors. The work was carried out by the U. S. Public Health Service (Division of Public Health Methods) and the National Institute of Health with the aid of grants from the WPA. The data were collected during the fall and winter months of 1935 to 1936.

The purpose of the investigation was to determine the incidence of disabling illness and accident, and their duration, the prevalence and type of chronic disease and defect, the amount of medical care received, and the relation of these factors to such other factors as income, relief status, employment status, occupation, housing conditions, education, sex, and color.

The reports are based on schedules taken in 84 cities for 740,000 families with 2,660,000 individuals, a number roughly equivalent to 3.7 per cent of the total urban population in 1930. In addition, 36,000 families with 140,000 persons were surveyed in 23 rural counties. The population sample was selected with the greatest care and in

such a way that it might fairly reflect the conditions prevailing in all parts of the United States.

The results of this investigation give us, without doubt, the best picture we have had up to date of the health conditions prevailing in all parts of the country. If it may be assumed that the sample population studied is typical of the entire population, the health status of the American people may be described in a few brief statements.

1. Six million people, 1 out of 20, are unable to work or attend school on each day during the winter months due to illness, injury, or physical impairment. Old people and children are ill more frequently than youth and middle age.

2. Of the 6 million disabled, the acute respiratory diseases account for approximately $1\frac{1}{2}$ million, one-fourth of the total. Chronic diseases are responsible for $2\frac{1}{2}$ million (more than 40 per cent); injuries due to accident for $\frac{1}{2}$ million; acute infectious diseases (mostly children) for 250,000; and acute diseases of the stomach and liver, and appendicitis for about 250,000.

3. During the period of a year 172 out of each 1,000 persons are disabled by illness or accident for 1 week or more. Applied to the whole population this gives 22 million cases of illness disabling for a week or more.

4. In the country as a whole about $\frac{1}{4}$ billion days are lost annually from work or school through illness. On the average this represents 10 days of disability for each person. The average duration of disability for each person per case of illness was 57 days. For those under 15 it was 26, while for those over 65 it was 123. Chronic illness counted for 138 days of disability per case.

5. There is a very significant relation between income status and the frequency of illness. The frequency rate was one and a half times as great for families on relief as it was for families with incomes over \$3,000. The frequency rate declined steadily for successively higher income groups. The greatest differences between income groups appears in the frequency of chronic illness.

6. Disabling illness is also more severe among those of low than of higher economic status. The average case of illness among those on relief was of 63 per cent longer duration than among those with incomes of \$3,000 and over. The greater frequency plus the greater severity of illness in relief families

gives rise to a volume of disability that is 3 times as great as in families of higher income status. The relation between illness and low income is partially revealed in the fact that 5.2 per cent of the heads of relief families reported themselves as not seeking work due to illness. Only 0.4 per cent of family heads in the \$3,000 class were so reported. The extremely high severity of chronic illness in the low income classes is particularly notable. The relief group showed a volume of disability twice that in the highest income group.

7. Families of low income status receive less care by physicians than do those with higher incomes. Thirty per cent of the cases of disabling illness were unattended by physicians in relief families. This figure declined at each income level. In families with incomes over \$3,000 it was 17 per cent. Measured in terms of the number of physicians' visits per case attended there were considerable differences in the volume of care enjoyed at each income level.

8. About 1 per cent of the relief families and 2.5 per cent of non-relief families with incomes less than \$2,000 received the services of a private duty nurse. The figure for those with incomes over \$3,000 was 12 per cent. On the other hand, low income families made considerably more use of the public health nurse. It is doubtful, however, if the public health nurse is an adequate substitute for the private nurse in cases of serious illness.

9. Cases of disabling illness were hospitalized more frequently in relief families than they were among non-relief families of limited incomes (less than \$1,000). Families with incomes of \$3,000 and over enjoyed hospital care more frequently, however, than did relief families. Preliminary analysis, however, seems to indicate that the greater volume of hospital care for relief families prevails only in the larger cities. In the small cities (less than 25,000) relief families received half the volume of hospital care enjoyed by families in the \$3,000 and over class. This fact reflects the greater inadequacy of free hospital service in the smaller cities.

This study deserves the wide interest which it has already attracted from the press and current periodicals. Its results confirm the picture of the nation's health which we have been getting from earlier but more fragmentary and local studies. That there exists an enormous volume of preventable disease, and that

present methods and facilities for meeting the problem are inadequate, seems an inescapable conclusion. No more convincing argument can be presented for the inclusion in our system of social security of an adequate program for health protection than the results of this investigation. Complete reports on the study will be awaited by all those interested in the problem of providing adequate protection against the hazard of illness. C. T. PIHLBLAD

Getting Ready To Be a Mother—
By Carolyn Conant Van Blarcom, R.N. (3rd ed.) New York: Macmillan, 1937. 305 pp. Price, \$2.00.

The third edition of Miss Blarcom's handy manual on prenatal and early infant care follows closely in content and format to the previous editions. However, there has been some rearrangement of the text and considerable new material has been added especially in the way of illustrations and chapters on habit formation. The fact that a new edition of this practical guide has appeared emphasizes the widening recognition of the importance of prenatal care and the desire on the part of parents to obtain the latest and best information available on this subject.

RICHARD A. BOLT

Les Microbes Anaérobies—*By M. Weinberg, R. Nativelle, and A. R. Prévot. Paris: Masson et Cie, 1937.*

No one will doubt that Weinberg and his associates have earned the right to the authorship of this textbook through their assiduous devotion to this group during two decades. The opportunity to review it is especially interesting because I had the good fortune to see, and in a few cases help correct and revise, the galley proofs in Paris in 1936.

Les Microbes Anaérobies is the most complete and accurate treatise upon the anaerobic bacteria that has ever

appeared in print. It is in a single volume of 7 parts, dealing successively (1) with the early discoveries of anaerobic bacteria by Pasteur and the subsequent developments of various technics for studying and cultivating them up to the present; (2) with the pathogenic Gram-positive anaerobic bacilli with central or subterminal spores among which are many of the important disease producing anaerobic microorganisms of man and animals; (3) with the anaerobic bacilli which form terminal spores, among which are *Bacillus tetani*, *Bacillus carnis*, some species not so clearly defined as pathogens, and many which are non-pathogenic; (4) this describes many species of Gram-positive anaerobic bacteria of little or no pathogenic significance. This brings together many supposed species whose present classification is questionable owing to the lack of adequate and critical descriptions, such as "*B. ramosus*," "*B. bifidus*," "*B. lymphophilus*," the "diphtheroid" anaerobes, the chromogenic anaerobes, and the "Streptobacilles," "Leptothrix," and "Streptothrix"; (5) this covers various Gram-negative anaerobic bacteria, "Batonnets," "Fusiformes," again "Leptothrix," "Vibrions et Spirilles," "Bacteroides," and other forms described inadequately; (6) devoted to anaerobic bacilli capable of fermenting complex carbohydrates such as cellulose, starch, and other polysaccharides; and (7) to the anaerobic cocci for whose detailed study Prévot has made himself mostly responsible.

There are appendices on the buccal spirochetes and the broncho-pulmonary anaerobes, on anaerobic bacteria overlooked until after the type was set, and on habitat, as well as a fairly complete bibliography.

The work is fairly well illustrated; many of the photographs of bacteria stained by Levinson to show flagella

are really fine. The paper is better than one finds in some French publications and the printing is good.

It lacks a well organized index and the attempted classification as indicated by the various parts is illogical. One might wish also for a more critical attitude in certain sections, but it seems clear that it was their intent mainly to record in one volume as complete a summary of the literature on the anaerobic bacteria as possible, not to settle the multitudinous problems of identity of species which exist; to compile principally, and to evaluate only where clear-cut indications permitted. In this they have succeeded eminently. *Les Microbes Anaérobies* fills a real need in the field of anaerobic bacteriology and ably supplements and supplants its excellent predecessor, *La Gangrene Gazeuse*, published by Weinberg and Seguin 20 years ago.

IVAN C. HALL

Twenty-five Years of Health Progress—By Louis I. Dublin and Alfred J. Lotka. New York: Metropolitan Life Insurance Co., 1937. 611 p.

When, in 1911, the Metropolitan Life Insurance Company inaugurated its health and welfare program, it placed in charge of the statistical investigations a man whose vision was not confined to the problems and requirements of the day. To say that the development of the philosophy and the perfection of the practice of vital statistics in this country in the last quarter of a century was, in an important degree, determined by the work of Dublin and his gifted associates, is stating a fact of general knowledge.

This work by Dublin and Lotka summarizes and evaluates "Twenty-Five Years of Health Progress" in terms of the experience of the Metropolitan Life Insurance Company and the available comparable material for the general population of the country. The out-

standing qualities are the integrity of statement, logic of deduction, and, what is so often lacking in American scientific work, good literary style. It is particularly gratifying to find few long range prophecies. Reasonably accurate quantitative measurements of morbidity and mortality became possible only recently. Although many diseases have exhibited sustained downward trends, in only very few—smallpox, typhoid fever, diphtheria—were there unquestioned cause-effect consequences. The mortality from scarlet fever, for example, has moved downward almost as rapidly as that from diphtheria. Here one might be tempted to attribute the reduction to public health activities, but the authors, with admirable reserve, merely state the hypothesis "that the causative organisms of the disease have exhibited a diminished virulence in recent years . . . and that we have no assurance that there will not be a reversion to the more virulent type." Similarly, in discussing the downward trend from measles, the authors find it "difficult to account for the marked decline in mortality."

The three introductory chapters: "An Era of Health Progress," "The General Mortality from All Causes," and "The Trend of Longevity through a Quarter Century," form a concentrated but very readable and ample introduction to the detailed discussion of the specific mortality by cause, in which individual chapters are devoted to tuberculosis, influenza and pneumonia, cancer, diabetes, and diseases of the puerperal state. The principal communicable diseases of childhood and the principal cardiovascular-renal diseases are considered as a group as well as individually. A chapter is given to "miscellaneous diseases of special interest," such as typhoid fever, syphilis, pernicious anemia, while the final chapter contains a comprehensive dis-

cussion of the external causes of death—suicide, homicide, and accidents.

The several chapters could be taken as excellent examples of sound objective statistical writing. The treatment of the complex influenza-pneumonia group is particularly excellent. An example of cogent reasoning is the discussion of the marked decline in the death rate from tuberculosis, heart disease, cerebral hemorrhage, and chronic nephritis which followed the influenza pandemic of 1918-1919. "There is," the authors say, "one seemingly obvious explanation," but they do not accept it because

. . . it is not borne out by the facts. It has often been supposed that this decline in death rates was merely a result of the wiping out by the epidemic, in one fell swoop, of a large number of physically impaired persons . . . This supposition . . . is not in harmony with the facts . . . For (1) the death rate from all causes at the older ages did not increase in 1918 as it would have done if there had been a weeding-out process of impaired persons at these ages, (2) the pandemic was notable for its high prevalence among younger people . . . Furthermore, the view that the pandemic was selective in its action against physically inferior persons is contradicted by the fact that there was high fatality among vigorous young men.

The authors then proceed to formulate several likely explanations, stressing, however, that they are all hypothetical.

An appendix to the book gives detailed statistical tables showing the distribution according to sex, race, age, and cause of the more than three million deaths recorded in 1911-1935 among the industrial policy holders of the Metropolitan Life Insurance Company.

For evident reasons, this book cannot become a "best seller," but it should, and one hopes will, be one of the most frequently consulted works in public health literature.

Copies of the book are available to a limited number of libraries and professionally interested people.

J. V. DePORTE

The Psychology of Eating—By *Lewis R. Wolberg, M.D.* New York: *McBride*, 1936. 321 pp. Price, \$3.00.

This omnibus of eating traces the dietary lore from the carnivorous cave-man down through the ages to the modern science so venerated by the stream-lined sylphs. On the way it passes through the facts, fads, and fancies which have had their day or which, persisting in part, may be recognized in current practice. From its title the book might be expected to explain why we eat as we do, or even to psychoanalyze aberrant dietary lives. But this theme is abandoned before it is fully developed. The author has used more psychology in writing the book than he has written into it.

While the book spreads over the entire domain of diet and nutrition, it is essentially dedicated to routing obesity. For those on the heavy side, every conceivable psychological stratagem would seem to have been included to meet their every type of resistance to dietary reform. The appeal to instincts, the stir of emotions, and the challenge to reason, all are here. It should reduce the inveterate gourmet or gelatinous backslider to a penitent mood. Thereupon it leads into the road to rehabilitation with its signposts of food values and sample menus.

The book covers much territory; therefore some of it must necessarily be superficial. Then too, its tone has an unevenness which can scarcely be escaped in such a panoramic treatment, for all parts of diet and nutrition do not lend themselves equally well to popularization. But its most noticeable blemishes are a certain lack of coherence at times, and an overindulgence in repetition.

On the whole, the style is agreeable and entertaining. In its exposition of dietetic principles, the book is sound; except for a few inaccuracies, it is likewise faithful to the science of nutrition.

But by all odds the book strikes its highest level in its scattered paragraphs on the psychological basis for food habits, which unfortunately were all too few. If the book's scope had been narrowed, and the reiterations deleted, the space could have been well used toward achieving what the book purports to be—an exposé of the psychology of eating. This variance need not discount what it actually does in its capable and conservative approach to a major dietary problem, obesity. To the diet conscious—and who is not—and particularly to those who are or would be watchful of the waistline, the book offers advice and help as practical yet as palatable as its menus.

H. D. KRUSE

The Management of the Pneumonias—By *J. G. M. Bullowa.* New York: *Oxford University Press*, 1937. 508 pp. Price, \$8.50.

Written out of a vastness of experience that alone must command respect, this book covers in a thoroughly comprehensive manner the entire subject of acute pneumonia. The author's experiences over a period of nearly 12 years, as chief of one of the largest pneumonia services in existence, are recorded in great detail with numerous illustrative charts and diagrams. Particularly valuable are Dr. Bullowa's records of age, anatomical form and bacteriology of some 6,000 cases, and his presentation of data concerning the use of antipneumococcus sera, especially in the treatment of the so-called higher types.

If the book deserves any criticism, it must be of the author's tendency to mix statements of soundly established fact with statements of theory without clear distinction. To the reader untrained in the field of pneumonia research, such usage will be found confusing.

The charts and diagrams are meaty in the extreme, but to our point of view

many of them are overly complicated and demanding of too much study.

Because of the wealth of experience it presents, this book must be considered outstanding among the monographs on pneumonia of the present day. It is probably too intricate for the use of the general practitioner, but it cannot be neglected by anyone presuming to a special knowledge of pneumonia. It should be on the reference shelf of every medical library.

EDWARD S. ROGERS

Practical Bacteriology, Haematology and Animal Parasitology—By E. R. Stitt, M.D., Paul W. Clough, M.D., and Mildred C. Clough. Philadelphia: Blakiston, 1938. 961 pp. Price, \$7.00.

It is a work of supererogation to criticise or to praise this book, which has reached its 9th edition. Years ago an English critic said that if a scientist interested in these lines were cast on a desert island and were limited to one book, Stitt is the one which he would select. This opinion, in one form or the other, the reviewer has heard echoed a hundred times, and it is his own opinion also. The preface states that the needs of the man in tropical or remote fields have been borne in mind as well as those who have access to well equipped libraries, and this is true.

The present edition appears in a new format, with two junior editors. It has been considerably revised. The chapter on Filtrable Viruses is practically new. A new chapter on the fungi has been added. The chapter on Immunity and Hypersensitiveness, especially the part dealing with allergy, has been largely rewritten. The greatest revision is found in the part devoted to hematology. Instead of the 67 pages on hematology and the 23 on chemical examinations of the blood, there are now respectively 95 and 56 pages. Some

colored plates have been added in this section.

It is hard to praise this book too highly. The present edition will hold its place with those which have preceded it, as being perhaps the most complete and practical book on the subjects treated on the market. The printing and make-up are good and the illustrations excellent.

MAZÛCK P. RAVENEL

Dr. Nash's Cookery Book—By Elwin H. T. Nash, M.R.C.S., M.R.C.P., Medical Officer of Health, Hounslow, England. London: Simpkin, Marshall, Ltd., 1937. 183 pp. Price, \$.50.

This book describes a research which was undertaken to see how far it was possible to provide a scientifically adequate diet with the requisite amount of first class protein by utilizing the cheap cuts of meat which are seldom used but which from the nutritional standpoint are good. The work was made possible by a grant of £500 from the Carnegie Trustees. Dr. Nash had a staff headed by Miss Hook, a nutrition worker of long experience who had studied dietetics in America as well as in England. He had one other well trained person and his own cook who had been studying Professor Mottram's writings. He personally sampled every dish that was prepared in addition to having a man and a woman from among the unemployed to pass judgment on them. He recognized that monotony of diet must be avoided and that to be useful the dishes must be palatable as well as nutritious.

It is astonishing to note that throughout his study the average price paid for beef was only 6d. per pound and for mutton only 3d. per pound. Most of the utensils used were bought at what we know in this country as 5 and 10 cent stores.

The author lays stress on the utilization of what are usually waste prod-

ucts: bacon scraps left after slicing, biscuit dust accumulating at the bottoms of tins, etc. He mentions one store in his district in which this averages 28 pounds per week, and points out its high nutritive value on account of the fat, sugar, carbohydrates, and proteins which it contains.

There are some 12 pages devoted to General Principles, while the rest of the

book is made up of recipes. We believe this is an unusually useful book. With some change of nomenclature, since the English use terms not generally understood in this country, the book would seem to have a place in providing a wholesome dietary for those who must economize strictly on food bills.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Attacking a Ten Billion Dollar Problem—Presenting the need for a national health program, this committee report comments upon the morbidity findings of the recent nation-wide sampling, points out the need for better maternal and child health services, more comprehensive public health administration, a better distribution of medical personnel and institutions, more public health nurses, ending with an emphatic plea for more hospitals in rural centers.

ANON. A National Health Program and Some Proposals Toward Its Design. *J.A.M.A.* 110, 9:656 (Feb. 26), 1938.

Supply and Demand for Medical Services—Suggestions for methods of determining in each county the treatment resources for the care of the medically indigent, and the number of families needing, but lacking medical services.

ANON. Outline for Proposed Plan of Study of Medical Care. *J.A.M.A.* 110, 7:77B (Feb. 12), 1938.

For More Accurate Mortality Reporting — Recommendations are made by the Committee on the Accuracy of Certified Causes of Death of the A.P.H.A. for the revision of the International List designed to omit inaccurate and obsolete terms and to meet needs of better analysis of certain diseases and conditions.

ANON. The Accuracy of Certified Causes of Death. *Pub. Health Rep.* 53, 5:172 (Feb. 4), 1938.

Plans for Better Maternal Hygiene—Reporting the findings of the Conference on Better Care for Mothers

and Babies of the Children's Bureau, which are, or should be, well known to every health worker, mention is made of the two outstanding and equally well organized needs, better obstetrical training for physicians and nurses, and improvement of public health services.

AMIDON, B. Women and Children Last. *Survey.* 74, 2:38 (Feb.), 1938.

Laboratory Diagnosis of Measles—In blood smears from measles cases inclusion bodies may be demonstrated in the white corpuscles, and these bodies may be grown in tissue cultures of blood and of specimens taken in the throat. These two papers will be of interest to other health workers, as well as to pathologists, because of the wide publicity given to the diagnostic possibilities of these and related studies.

BROADEHURST, J., *et al.* Measles Inclusion Bodies in Blood and Tissue Cultures and Tissue Cultures of Human Throat Inclusion Bodies. *J. Infect. Dis.* 62, 1:6 (Jan.-Feb.), 1938.

Immunizing Babies — Diphtheria toxoid given at 6 months is as effective as that given at 1 year. Three doses of toxoid amounting to 2 c.c. is as protective as a larger amount, and the intervals between doses are not important.

BENJAMIN, B., *et al.* Results of Schick Test in Five Thousand One Hundred Ninety-five Children Given Injections of Diphtheria Toxoid. *Am. J. Dis. Child.* 55, 1:51 (Jan.), 1938.

Controlling Minor Contagious Diseases—Something about lice, scabies, ringworm, impetigo, and the other items that serve to make the school nurse's life such a merry one.

In 1914, skin diseases were found 42,000 times in New York school children; in 1936, with a much larger enrollment, only 11,000 cases were discovered. A much greater decrease in pediculosis was found, too.

COTTON, S. R. Common Skin Diseases in the Schools. *Pub. Health Nurs.* 30, 2:120 (Feb.), 1938.

Sewage and Garbage Disposal—

Though its subject be far removed from the routine duties and interests of most health workers, this paper on sewage and garbage is so ably written, and quite strangely—considering the topics—often amusing and entertaining, that it is highly recommended to all. A little knowledge of the general subject will hurt none of us.

CORN, M. M. The Disposal of Sewage and Garbage—Related Municipal Functions. *Sewage Works J.* 10, 1:81 (Jan.), 1938.

Life on the Ohio—How 5 million downstream residents drink the insufficiently diluted sewage of 2 million Pittsburghers is graphically told. Acid from mine drainage apparently helps to make the sewage a little less offensive, but the cities below Pittsburgh add their sewage to the mess without benefit of additional mine acids.

CROHURST, H. R. The Pollution Problem in the Ohio River Drainage Basin. *Pub. Health Rep.* 53, 4:121 (Jan. 28), 1938.

Debunking Malnutrition—Physicians differ so greatly in their judgment of nutritional status of children made in routine examinations that such findings are of limited value in determining administrative policies or estimates of malnutrition. Programs to correct faulty habits rather than physical examination campaigns will prove of greater usefulness until valid methods of determining nutritional status are perfected.

DERRYBERRY, M. Reliability of Medical Judgments on Malnutrition. *Pub. Health Rep.* 53, 7:263 (Feb. 18), 1938.

Advice for Epidemiologists—If repeated skin tests for susceptibility to scarlet fever are to be made on the same person, the previous sites should be avoided, for local immunity, as distinguished from general immunity, may be produced by intradermal injections.

DICK, G. F., and DICK, G. H. Local Immunity to Scarlet Fever. *J. Infect. Dis.* 62, 1:83 (Jan.-Feb.), 1938.

Sobering Statistics About the Curability of Active Tuberculosis—Although the incidence and the mortality rate of tuberculosis have declined, there has been no appreciable change in the ratio of deaths to reported cases in the past 20 years. Sanatorium treatment seems to have had but little effect upon case fatality rates even though segregation of cases has been a factor in limiting the spread of infection.

DROLET, G. J. Present Trend of Case Fatality Rates in Tuberculosis. *Am. Rev. Tuberc.* 37, 2:125 (Feb.), 1938.

All about Vitamins—Introducing an extended series of articles on the vitamins by acknowledged authorities, this paper wisely points out the many things vitamin products will not do, as well as their value in nutrition. The succeeding papers, which promise to be of great value to the health worker who is at all concerned with nutrition, will not be mentioned individually here.

FISHBEIN, M. New Series of Articles on Vitamins. Introduction. *J.A.M.A.* 110, 8:577 (Feb. 19), 1938.

Saratoga, et al. Nota Bene—Evidently British health authorities are boosting the spa in a big way, for here are a half dozen papers on the watering place as an aid to health promotion. As the United States is plentifully supplied with such institutions both inland and on three seaboard, it is to be wondered at that American health

officials have not been called upon to come to their aid too.

HORDER, *et al.* The Spa as a National Asset in the Maintenance of Physical Fitness. *J. Roy. Inst. Pub. Health & Hyg.* 1, 5:274 (Feb.), 1938.

Active Immunization with Meningococcus Toxin — Experience in Missouri CCC Camps with meningococcus toxin used as a prophylactic leads the authors to urge its trial elsewhere. Although 26 cases of epidemic meningitis have occurred in the state camps, none of the immunized group has succumbed.

KUHNS, D. M., *et al.* The Control of Meningococcic Meningitis Epidemics. *J.A.M.A.* 110, 7:484 (Feb. 12), 1938.

A Shoe to Fit Many a Foot—Brief but brilliant, this discussion of selling public interest in public health administration and health practice should be on everyone's "must" list. The last paragraph might well be displayed on every local health department bulletin board.

MARQUETTE, B. Public Relations for Public Health. *Health Officer.* 2, 9:418 (Jan.), 1938.

Preventing Deformities in Polio—From Australia comes word that our orthodox methods of treating poliomyelitis are wrong, for complete rest induces atrophic changes. In the method proposed, passive exercise of affected limbs is carried on even during the pyrexial stage. Local heat is applied, and in a bath, hot and cold sprays are used. The scheme is being tested in England.

MILLS, F. H. Treatment of Acute Poliomyelitis. *Brit. M. J.* Jan. 22, 1938, p. 168.

Motes in Neighbor's Eyes—For those who enjoy a secret sense of superiority, this article about British milk supplies will prove interesting and gratifying reading. It seems that milk producers are grossly underpaid, that

only a tiny part of the country's herds are tuberculin tested, and that compulsory pasteurization is still stoutly resisted. As so large a proportion of market milk samples contain tubercle bacilli, health officials cannot but warn the public, and hence the average per capita consumption, which lies between $\frac{1}{3}$ and $\frac{1}{2}$ pint per day, is not likely soon to be increased.

PRIESTLY, H. The Future of the Milk Supply. *J. Roy. San. Inst.* 58, 8:522 (Feb.), 1938.

Serum Treatment and Bedside Nursing—Stressing the importance of adequate nursing care in pneumonia, this paper is a useful addition to the recent literature devoting so much space to Neufeld typing and serum treatment of certain types of pneumococcus pneumonia.

ROGERS, E. S., and MACCHESNEY, E. H. Public Health Nursing Aspects of Pneumonia Control. *Pub. Health Nurs.* 30, 2:74 (Feb.), 1938.

How to Judge Malnutrition and What To Do about It—Here is something to announce to mothers clubs, parent-teacher associations, etc., when it is desirable to create a sensation. The writer, who is an authority, holds that the child who has a long morning school session from 8 to 1 needs a mid-morning lunch, but the practice of giving milk then is unscientific and often does more harm than good. The child who has his luncheon at 12 should have something to eat after school. When he should have milk, and a great deal more useful advice, will be found in the article.

SMITH, C. H. Malnutrition in Childhood. *Prev. Med.* 7, 11:257 (Feb.), 1938.

Social Hygiene's Main-Spring—Biographical material about William F. Snow, contributed by a large group of his admirers.

Souvenir Number. *J. Social Hyg.* 23, 9:473 (Dec.), 1937.

ASSOCIATION NEWS

SIXTY-SEVENTH ANNUAL MEETING

Kansas City, Missouri

October 25-28, 1938

HEADQUARTERS—MUEHLEBACH HOTEL

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Isaac P. Barrett, M.D., 310½ W. 10 St., Fort Worth, Tex., Assistant Director, Dept. of Public Health and Welfare
J. Douglas Barry, M.D., 934 Paulding St., Peekskill, N. Y., Health Officer
James M. Cameron, M.D., M.P.H., Dept. of Health, Fredericton, N. B., Canada, District Medical Health Officer
Peter Cohen, M.D., Santa Barbara County Health Dept., Santa Maria, Calif., Deputy Health Officer
Leon A. Dickerson, M.D., Fayetteville, W. Va., Fayette County Health Officer
Albert S. Dix, M.D., Scottsboro, Ala., Jackson County Health Officer
Lloyd M. Farner, M.D., C.P.H., City and County Bldg., Provo, Utah, Director, Health District 4, State Board of Health
Charles R. Gillespie, M.D., Indianola, Miss., Director, Sunflower County Health Dept.
Roy W. Harrell, M.D., Box 161, Carbondale, Ill., District Health Supt., State Dept. of Public Health
Floyd I. Hudson, M.D., Sussex County Health Unit, Georgetown, Del., Deputy State Health Officer
Gerard C. Leger, M.D., D.P.H., Buctouche, N. B., Canada, District Medical Health Officer, New Brunswick Dept. of Health
Herbert L. Logan, M.D., Main St., Sussex, N. B., Canada, District Medical Health Officer, New Brunswick Dept. of Health
Lt. Col. Charles L. Maxwell, M.D., Nichols Field, Manila, P. I., Medical Officer, U. S. Army
Howard L. McMartin, M.D., 1316 N. 10th, Boise, Idaho, Director, State Division of Public Health

Harry E. McTyre, 313 W. 37 St., Savannah, Ga., Bullock County Commissioner of Health
Richard Monahan, M.D., D.P.H., Campbellton, N. B., Canada, District Medical Health Officer, New Brunswick Dept. of Health
Roger Murray, M.D., 613 W. 10 St., Wilmington, Del., Executive Secretary, Board of Health
Thomas B. Phinzy, M.D., 501 Greene St., Augusta, Ga., Richmond County Commissioner of Health
Robert H. Riedel, M.D., State Board of Health, Topeka, Kans., Director, Venereal Disease Control, State Board of Health
Saul Ruby, M.D., C.P.H., 3521 Kite St., San Diego, Calif., Assistant to Director of Public Health
Glen T. Smith, M.D., Bannock County Health Unit, Pocatello, Idaho, Medical Director
Charles B. Stephens, M.D., City Health Dept., Topeka, Kans., City Health Officer

Laboratory Section

Beverly C. Booth, 1901 Ryons St., Lincoln, Nebr., Trainee—Sanitarian
Gertrude S. Boyer, 117 S. Boulevard, Oak Park, Ill., Junior Bacteriologist, State Dept. of Public Health
Samuel R. Damon, Ph.D., 517 Dexter Ave., Montgomery, Ala., Director of Laboratories, State Board of Health
Mary M. Dauch, International House, Berkeley, Calif., Laboratory technician—student at present
George G. DeBord, Ph.D., 5336 Colorado Ave., N.W., Washington, D. C., Associate Bacteriologist, District of Columbia Health Dept.

- Harry M. Eudowe, 1175 Chapel St., New Haven, Conn., Director, Eudowe Clinical Laboratory
- Warren C. Eveland, Box 561, Juneau, Alaska, Director, Division of Laboratories, Territorial Dept. of Health
- Herman A. Fisher, 420 Sixth Ave. N., Nashville, Tenn., Laboratory technician, State Dept. of Public Health
- Dorothy E. Ford, Cheswold, Del., Laboratory technician, State Board of Health
- Kenneth Goodner, Ph.D., Rockefeller Inst. for Medical Research, York Ave. & 66 St., New York, N. Y., Bacteriologist
- Eleonore Gottlieb, 4735 Lewis Place, St. Louis, Mo., Bacteriologist, City Health Dept.
- Thomas H. Grainger, Jr., Sharp & Dohme, Glenolden, Pa., Research Assistant, Technical Div.
- Margaret W. Higginbotham, D.Sc., Minneapolis Dept. of Health, University Campus, Minneapolis, Minn., Bacteriologist
- William F. Hutson, State Dept. of Public Health, Nashville, Tenn., Bacteriologist, Div. of Laboratories
- Vivian Jurist, 105 W. 72 St., New York, N. Y., Bacteriologist, Pyridium Corp.
- George Kucker, 14 Race St., Hillside, N. J., Medical Technologist and Chemist, Elizabeth Bio-Chemical Laboratory
- Edward C. Link, Pathological Institute, Memphis, Tenn., Bacteriologist
- Margaret B. Lindsay, 117 S. Boulevard, Oak Park, Ill., Junior Bacteriologist, State Dept. of Public Health
- Harvard C. Luke, 148 Pierce Ave., Twin Falls, Idaho, Laboratory technician, South Central District Health Unit
- James M. Neill, Ph.D., 1300 York Ave., New York, N. Y., Research in Bacteriology, Cornell University Medical College
- Ruth D. Northey, Yale Univ. Dept. of Health, New Haven, Conn., Laboratory Assistant
- Gordon R. Reeves, State Board of Health, Jackson, Miss., Bacteriologist, State Hygienic Laboratory
- Rita A. Robinson, R.F.D. 2, Box 312, Oklahoma City, Okla., Bacteriologist, Central Laboratory, State Dept. of Health
- Doris L. Roddan, San Joaquin General Hospital, French Camp, Calif., Assistant Laboratory technician
- Charles Schwartz, Ph.D., 5630 Hobart St., Pittsburgh, Pa., Research Chemist, Calgon, Inc.
- Carol C. Schweiss, International House, Berkeley, Calif., Laboratory technician—student at present
- Orton K. Stark, Ph.D., Miami University, Oxford, O., Assistant Professor of Bacteriology
- Frank H. Stubbs, 401-8 St., Albany, Ga., Director, Branch Laboratory, State Dept. of Health
- Earl J. Sunkes, Dr.P.H., State Dept. of Health, Atlanta, Ga., Assistant Director of Laboratories
- Wheelan D. Sutcliff, M.D., William H. Park Laboratory, Foot of E. 15 St., New York, N. Y., Assistant Director, Pneumonia Control
- Elizabeth Wilson, Michigan Dept. of Health Laboratories, Lansing, Mich., Junior Bacteriologist
- Ben M. Zakariasen, Rm. 552, State Office Bldg., St. Paul, Minn., Chief Chemist, Dept. of Agriculture, Dairy and Food

Vital Statistics Section

- Edward P. Conaty, 80 Dover St., Providence, R. I., Fiscal Officer, State Dept. of Public Health
- Robert G. Webster, Rm. 162, Hall of Justice, Los Angeles, Calif., Chief, Div. of Vital Records, Los Angeles County Health Dept.

Public Health Engineering Section

- Hayse H. Black, 1605 S. Douglas Ave., Springfield, Ill., Assistant Sanitary Engineer, State Dept. of Public Health
- Edward S. Brown, Jr., C.E., 13 Balch St., Hanover, N. H., Instructor in Sanitary Engineering, Thayer School
- Charles G. Caldwell, 3525 Life Sciences Bldg., Berkeley, Calif., Student at present—District Sanitarian in New Mexico
- Ellsworth F. Clements, Box 429, Juneau, Alaska, Sanitarian, Territorial Dept. of Health
- Charles E. Gotta, 454 E. Second St., Caspian, Mich., Sanitarian, Iron County Health Dept.
- Herbert A. Jewett, 727 W. Arden Ave., Glendale, Calif., Chief, Div. of Water and Sewage, Los Angeles County Health Dept.
- John N. Johnson, State Board of Health, Raleigh, N. C., District Sanitarian
- Silvio D. Mastroianni, 728 W. 5 St., Reno, Nev., Student
- Noel McKeehan, Rm. 9, Court House, Phoenix, Ariz., Sanitarian, Maricopa County Health Unit
- Curtis E. Moutrey, Koy County Public Health Dept., Newkirk, Okla., Sanitarian
- Walter A. Reiman, State Board of Health, Little Rock, Ark., Assistant Sanitary Engineer
- Paul E. Seuser, C.E., 1412 Smith Tower, Seattle, Wash., Assistant Public Health Engineer, State Dept. of Health

Lawrence R. Tabor, P. O. Box 676, Thomasville, Ga., Sanitary Engineer, Thomas County Health Dept.

George A. Warren, Broward County Health Dept., Ft. Lauderdale, Fla., Sanitary Officer

James M. Welsh, Division of Public Health, Boise, Idaho, Senior Sanitarian

William W. White, 812 W. First St., Reno, Nev., State Sanitary Engineer

Industrial Hygiene Section

Lewis B. Case, 18721 Gainsborough, Detroit, Mich., Chemist, Research Laboratories Div., General Motors

Arthur L. Nichols, Jr., University of Kansas, Lawrence, Kans., Industrial Hygiene Technologist, State Board of Health

 John N. Ryan, M.D., Passaic, N. J., Elected Member 1915

ROYAL SANITARY INSTITUTE

THE Royal Sanitary Institute will meet in Portsmouth, England, July 11-16.

The Executive Secretary of the A.P.H.A. desires to know of any Fellows of the Association who plan to be in England during this period.

CONFERENCE ON THE HEMOLYTIC STREPTOCOCCI

THE Coördinating Committee of the Laboratory Section, under the Chairmanship of Lieutenant-Colonel A. Parker Hitchens, recently sponsored a conference to discuss methods for the identification, study, and taxonomy of the hemolytic streptococci. The 19 persons in attendance were representative of organizations and agencies interested in the subject. The discussions are reported in 26 mimeographed pages. A limited number of copies of the

report are available upon application to the Executive Office.

PUBLICATIONS NEEDED

THE Association stock of these issues of the *Journal* is almost depleted:

January, 1937
 February, 1937
 January, 1938

If any members can spare copies of these numbers, the Executive Office will much appreciate it if they will kindly send them to headquarters, at 50 West 50th Street, New York, N. Y.

CORRECTION

ON page 147 of the February *Journal* (Sanitary Aspects of Air Conditioning, by C. P. Yaglou), reference 11 should be "March, 1938," instead of "March, 1937."

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., C.P.H.; 2 years' experience as district health officer; anxious to do venereal disease control work or epidemiology. A345

Physician, M.D., Northwestern University; Dr.P.H., Yale; will consider appointment in general administration, infant welfare or epidemiology. A300

Physician, M.D., Johns Hopkins; public health course at Michigan; experienced in school and city health work, will consider an administrative post in eastern United States. A354

Trained administrator, A.B., M.D., with background of laboratory and research; formerly assistant health commissioner large city. Familiar with all lines. Available short notice. A295

Physician, M.D., University of Maryland; C.P.H., Johns Hopkins; broad experience in county public health administration, will consider opening of better class. A346

Physician, M.D., Tufts; C.P.H., Johns Hopkins; administrative experience large city health department, will consider position as health officer or epidemiologist. A362

CHILD HYGIENE

Experienced physician, M.D. and Ph.D., University of Minnesota; specially qualified in maternal and child hygiene, directing state and local programs; will consider position of better sort. A238

Woman physician, M.D., Yale; Dr.P.H., Yale; experienced in pediatrics and adminis-

tration of state bureau, will consider attractive opening. A348

MISCELLANEOUS

Experienced teacher, B.S., Massachusetts Institute of Technology; graduate courses, Harvard School of Public Health; wishes position or will consider statistical or health education opportunity. M353

Certified teacher of Hygiene and Health Education; man, age 35, M.S. in Education, also graduate studies at Teachers College, Columbia and Massachusetts Institute of Technology, seeks appointment to teach or supervise effective program in Personal and Community Hygiene. M360

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Young man, Sc.D., Johns Hopkins; experience in public health and research bacteriology; will consider position in public health work or university teaching. L312

Young man, at present college teacher of hygiene and physical education and experienced in university medical service, desires position as executive in public or private health organization. M357

Young woman, Ph.D., Yale University, experienced in the field of bacteriology and immunology, will consider a position in health organization, education or the administrative field. M324

Pediatrician: Graduate of Syracuse University; internships and postgraduate work in pediatrics in United States and Europe; teacher in large eastern medical college; author of textbook on infant nutrition; considerable experience in city health department in infant welfare and child health, juvenile tuberculosis, and epidemiology. Will consider position in teaching, or in infant welfare, child health, or other public health work. M361

NEWS FROM THE FIELD

ANTI-SYPHILIS COMMITTEE

MORE than 1,200 men and women representing business and the professions are aligned with General John J. Pershing, chairman of the National Anti-Syphilis Committee of the American Social Hygiene Association, in the \$500,000 fund campaign for the Association's program against syphilis, especially among youth, and the conditions which favor its spread.

These men and women are serving either on the national committee which numbers 271 or one of the 16 state committees in the 5 areas of the campaign. Through the activity and endorsement of these leaders, General Pershing's committee has been enabled to show a total of almost \$150,000 in gifts and pledges.

With several weeks yet remaining for the appeal, indications are that the required sum will be obtained.

INSPECTION OF DIAGNOSTIC LABORATORIES

A PLAN to inspect and appraise the public and private diagnostic laboratories in Illinois has been announced by the State Department of Health. The immediate object is to improve and standardize laboratory tests for syphilis.

Each laboratory that volunteers to participate in the plan will be inspected at intervals by a representative of the department. Assistance will be offered when needed, and standard antigen for making blood tests for syphilis will be provided by the department. Certificates of approval will be issued to each laboratory maintaining the required technical and professional standards and a register of all approved laboratories will be kept. There are about 225 of these laboratories in the state.

THE HENRY ROSE CARTER MEMORIAL LABORATORY

ON February 8, 1938, the Henry Rose Carter Memorial Laboratory was dedicated at Savannah, Georgia, in honor of the late Assistant Surgeon General, Henry Rose Carter (1853-1925), of the United States Public Health Service. The land, building and equipment were made possible through funds authorized by the city administration. Construction was effected through the WPA, according to the plan of the Director, Senior Surgeon T. H. D. Griffiths, who was assisted by Mr. Kinyon, of the City Health Department. The laboratory was presented to the United States Public Health Service and will be used for malarial research.

It is a fitting memorial to one of the world's greatest sanitarians and investigators of malaria and yellow fever, much of whose work may have been forgotten by the present generation.

Summarizing the outstanding contributions of Dr. Carter to public health and sanitation, they are: (1) the determination of the correct incubation period of yellow fever; (2) the determination of the extrinsic incubation of that disease; (3) establishment of its place of origin in Africa; and (4) his introduction of successful malaria control measures in the United States. Many of his papers on malaria control were published in early volumes of the *Southern Medical Journal*.

It is fitting that a testimonial to his achievements should be in the form of a malarial research laboratory, since his views have been accepted internationally and his preventive methods adopted throughout the world. Savannah is to be congratulated upon fostering this institution. Many young

Americans today are ignorant of or may consider lightly the great service which the Army and Navy medical corps have rendered the world in sanitating uninhabitable lands and making them safe for human beings. It is appropriate that it be kept in mind by a tribute of this type to an illustrious name.—*Southern Med. J.*, Mar., 1938.

"COOPERATIVE HEALTH"

COOPERATIVE HEALTH will be the title of a magazine to be launched this spring as the official monthly publication of the Bureau of Coöperative Medicine, Coöperative League of the United States. Farm, labor, medical and social welfare leaders will serve as advisers on the Board of Consultants for the journal.

Michael M. Davis, Ph.D., Chairman of the Committee on Research and Medical Economics, will head the Board. Representatives from the social welfare and medical fields include: Edith M. Gates, National Y.W.C.A. health education secretary, Dr. C. Rufus Rorem, Dr. C.-E. A. Winslow, Dr. Henry Sigerist, Mrs. Miriam Steep, and Carl Malmberg, editor of *Health and Hygiene*, who will act as consulting editor. Editorial policy of the new magazine will be directed toward coordinating the many steps toward coöperative medicine now being taken in this country, according to Martin W. Brown, secretary of the bureau.

PNEUMONIA SERA

ACCORDING to Dr. Edward S. Godfrey, Jr., New York State Commissioner of Health, "unfortunate" and "premature" publicity giving the impression that the use of rabbit sera in the treatment of pneumonia will soon result in the availability of sera highly effective against all of the 50 different types of the dis-

ease, is without scientifically accepted supporting evidence.

However, Dr. Godfrey said, it must be understood that his criticism is directed against "premature use of a new product" and not in any way intended to discredit its ultimate usefulness or the present value of anti-pneumococcus horse sera, now recognized as of great value and, in fact, provided for physicians by the state.

Dr. Godfrey also made public a resolution of the state's advisory committee on pneumonia control, urging against jeopardizing the future of anti-pneumococcus rabbit serum as a practical method of pneumonia treatment by its "premature generalized use."

CAIRO LEPROSY CONFERENCE

AMONG the distinguished physicians representing the United States in the Fourth International Leprosy Conference in Cairo, Egypt, were: H. E. Hasseltine, M.D., Victor G. Heiser, M.D., James A. Doull, M.D., and George M. Saunders, M.D.

N.O.P.H.N. INSTITUTES

THE National Organization for Public Health Nursing has planned a series of Institutes for the Saturday and Sunday just prior to the Biennial Convention to be held in Kansas City, Mo., April 24-29. The following subjects will be covered at individual institutes:

Records and Statistics, Syphilis and Gonorrhea, Maternity, School Nursing, Tuberculosis, and Business and Office Administration.

Attendance at each institute is limited. Registrations stating name, address, positions, N.O.P.H.N. membership, name of institute, and enclosing registration fee of \$3.00, should reach the N.O.P.H.N. office, 50 West 50th Street, New York, N. Y., before April 10.

INTERNATIONAL HEALTH BROADCAST

LEADING British and American physicians, 6,000 miles apart, will confer via the radio on a great menace to child health, rheumatic heart disease. This conference, one of the first international broadcasts on health problems, will be heard over the National Broadcasting Company, WEAf and the Red Network, on Monday evening, May 2, at seven thirty o'clock Eastern Daylight Saving Time. Arranged by the American Heart Association, New York City, the conference-broadcast will observe National Child Health Day.

Lord Thomas Jeeves Horder, Physician-in-ordinary to the King of England, will open the conference, speaking from London. Dr. Homer F. Swift of the Rockefeller Institute, New York City, and Dr. T. Duckett Jones of the House of the Good Samaritan, Boston, will then speak from Atlantic City where they will be attending the convention of the American Society for Clinical Investigation. Dr. William J. Kerr, President of the American Heart Association, will take up the discussion from San Francisco.

COLORADO PUBLIC HEALTH ASSOCIATION

IN March, Platt W. Covington, M.D., of Salt Lake City, President of the Western Branch, American Public Health Association, met with the Council of Allied Health and Welfare Associations of Denver to discuss the creation of a Colorado State Public Health Association. It was decided to organize a Colorado Public Health Association from the Allied Association and a constitution was adopted by those present who agreed to stimulate membership in the state and national organization from among those professionally engaged in public health work in Colorado.

INDIAN SERVICE CEREMONIES

DR. W. W. Peter, Medical Director of the Navajo-Hopi Areas, has called attention to the fact that the new United States Indian Service base hospital of 130 beds, costing \$450,000, will be dedicated at Ft. Defiance, Ariz., on Monday, June 20. Three days of clinics will follow.

An invitation is extended to physicians and public health workers who might route their return by Ft. Defiance over the Santa Fe Railroad or by transcontinental highway 66, after attending the annual meetings of the Western Branch of the Association in Portland and the American Medical Association in San Francisco. Dr. Peter, whose address is Window Rock, Ariz., offers to arrange tours over the 25,000 square mile reservation, visiting other hospitals and points of scenic and public health interest after the dedication and clinic days.

NATIONAL NEGRO HEALTH WEEK

THE Twenty-fourth annual observance of National Negro Health Week will occur April 3 to April 10, with a special objective for the year, "The Family Doctor's Opportunity in Community Health Service."

As in previous years, the plans for Negro Health Week are under the direction of a national committee co-operating with the United States Public Health Service, Washington. Roscoe C. Brown, D.D.S., is in charge.

TUBERCULOSIS CAMPAIGN IN CUBA

THE Cuban Government has recently allotted \$1,000,000 from its lottery funds for a campaign against tuberculosis, the *Health Officer* reports. Clinics are to be established throughout the country for examinations, which will be carried out on every citizen. Edgar Mayer, M.D., and Morton

C. Kahn, Ph.D., of New York, recently visited the island to help establish the first clinics. With Wilson G. Smillie, M.D., New York, they will return periodically to advise on the work, it is said. L'Esperanza Hospital near Havana has been renovated for the care of tuberculous patients and a new hospital is being built near Trinidad.

HEART DISEASE LEADS IN INSURANCE CLAIMS

FOR the 14th year in succession, more money was paid out for deaths from organic heart disease than for any other cause of death. The huge sum so disbursed last year (\$29,500,000, in round numbers) represents 17 per cent, or more than one-sixth of the total death claim payments of the company. The per cent of the total paid out year by year for deaths from cardiac conditions has been increasing almost continuously. Both physicians and public health workers know that a good share of the heart disease cases which result fatally year after year could be prevented or postponed, namely those of chronic endocarditis, which have their origin, very often, in the infectious diseases of childhood, in acute rheumatism and in syphilis. . . .

In addition to the death claim disbursements on account of cardiac diseases, close to \$21,000,000 was paid out in 1937 for 2 nearly related conditions, chronic nephritis and cerebral hemorrhage. These diseases often occur concurrently with heart disease. Thus the 4 principal cardiovascular-renal impairments combined were responsible for about \$40 out of every \$100 disbursed for all death claims last year.

Cancer ranked second in importance among all the causes of death and accounted for nearly 12 per cent of all the money paid out in death claims. Ten years ago it was responsible for a little

more than 9 per cent. It is interesting to note also that in 1927 the company disbursed more money on account of tuberculosis than on account of cancer, whereas in 1937 disbursements for cancer totaled two and one-third times those for tuberculosis. . . .

Tuberculosis ranked eighth, with claim payments of \$8,720,000. Tuberculosis is an outstanding example of a disease that is yielding steadily to an efficiently organized and administered movement for control. . . . Within that period (10 years) the per cent paid out has dropped from 10.3 to 5.0, and the actual sum disbursed in 1937 was lower than in 1927 by nearly \$1,700,000, despite the fact that lives of policy holders exposed to risk have increased within these years by more than 4,000,000. . . . —*Stat. Bull.*, Metropolitan Life Ins. Co. Feb., 1938.

MEDAL AWARDED DR. SCHICK

THE medal of the New York Academy of Medicine has been awarded to Dr. Bela Schick, who originated the Schick Test 25 years ago.

Dr. Schick, who is a native of Hungary, is a graduate of the Medical School at Graz, Austria. Since 1923 he has been Pediatrician-in-chief at Mt. Sinai Hospital. He is also Clinical Professor for Diseases of Children at Columbia University.

GEORGIA COUNTY UNITS

FIVE new county departments of health were recently opened in Georgia, and two additional counties will be opened as units as soon as qualified commissioners of health can be secured.

New Commissioners have been appointed as follows:

Dr. Henry T. Adkins—Blacky County
Dr. Harry E. McTyre—Bullish County
Dr. Roy L. Johnson—Coffee County
Dr. Johnnie L. Gollum—Dade County
Dr. John L. Dorsey—Wilkes County

MISSISSIPPI HEALTH LIBRARY

THE Mississippi State Board of Health, Jackson, Miss., announces a gift of over 1,200 volumes to the Medical and Public Health Library, from Dr. W. A. Evans, of Aberdeen, Miss., for many years Health Officer of Chicago.

The Mississippi State Board of Health library was started about 2 years ago, with 5,000 volumes.

NATIONAL HEALTH COUNCIL OFFICERS

NEW officers of the National Health Council, New York, N. Y., for 1938, are announced as follows:

President—Professor Ira V. Hiscock, Yale University, New Haven, Conn.

Vice-President—Dr. Walter Clarke, A.S.H.A., New York, N. Y.

Secretary—Dorothy Deming, N.O.P.H.N., New York, N. Y.

Treasurer—Frederick Osborn, American Eugenics Society, New York, N. Y.

Reëlected to the Board of Directors for a three-year term are: Donald B. Armstrong, M.D., whose term as President has just expired; Professor M. A. Bigelow, Kendall Emerson, M.D., Livingston Farrand, M.D., Homer Folks, Stanley H. Osborn, M.D., and William F. Snow, M.D. Dr. H. N. Marvin was elected delegate at large.

NEW OFFICERS OF NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

AT its last annual meeting on February 19, 1938, the Northern California Public Health Association elected the following officers:

President—Ida May Stevens, San Francisco

President-Elect—Louis Olsen, Palo Alto

Vice-President—Dr. H. E. Bingham, Woodland

Treasurer—Helen Hartley, Stockton

Secretary—Dr. I. O. Church, Oakland

Representative to the Regional Board of the Western Branch, A.P.H.A.—Dr. H. L. Wynns, San Francisco

Representative on A.P.H.A. Governing Council—Dr. Fred T. Foard, San Francisco

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION ELECTS NEW OFFICERS

NEW officers of the Southern California Public Health Association, elected at its last annual meeting on January 31, 1938, are as follows:

President—Dr. G. E. McDonald, Long Beach

President-Elect—Dr. Alex M. Lesem, San Diego

First Vice-President—Dr. Wilton L. Halverson, Pasadena

Second Vice-President—Dr. C. Morley Sellery, Los Angeles

Secretary-Treasurer—Dr. R. L. Kaufman, Whittier

INDUSTRIAL PHYSICIANS MEETING

THE meeting of the American Association of Industrial Physicians and Surgeons will be held concurrently with the Midwest Conference on Occupational Diseases, at the Palmer House, Chicago, Ill., June 6-9.

PERSONALS

Central States

DR. CHARLES ALBERT ARNESON, of Bismarck, N. D., has been named Health Officer of Bismarck.

CHARLES H. P. G. BENNING, M.D., C.P.H.,* of Peoria, Ill., has been appointed District Health Officer of Royal Oak, Mich., a position he held prior to his appointment as School Physician in Peoria.

BENJAMIN LIEBERMAN, M.D.,† has been appointed head of the School Hygiene Division of the Milwaukee Department of Health, to succeed the late GEORGE P. BARTH, M.D.*

DR. JOSEPH F. MICHAELS, of Loogootee, Ind., has been appointed Health Officer of Marion County.

DR. ERNEST V. NOLT, of Columbia City, Ind., has been appointed Health Officer of Whitley County.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. JOHN R. PENCE, of Minot, N. D., has been appointed Health Officer of Ward County.

HOWARD J. SHAUGHNESSY, PH.D.,† formerly with the Department of Bacteriology and Public Health of the University of Illinois College of Medicine, has been appointed Associate Professor of Bacteriology and Public Health in the University of Colorado, Denver. He succeeds SEVERANCE BURRAGE, PH.D.,* who has retired.

Eastern States

LEAH M. BLAISDELL, R.N.,* formerly Educational Supervisor, Division of Public Health Nursing, New York State Health Department, has joined the staff of the Henry Street Visiting Nurse Service, New York, N. Y., as Educational Director.

DR. EUGENE N. COZZOLINO has been appointed Health Officer of West Haven, succeeding the late Dr. CHARLES E. KAUFMAN.†

JOHN S. CUNNINGHAM, M.D.,† formerly Epidemiologist in the Connecticut State Department of Health, has been appointed District Health Officer in charge of Livingston, Monroe, and Wayne Counties, New York.

J. J. GOLUB, M.D.,† Executive Director of the Hospital for Joint Diseases of New York, has been appointed by Governor Herbert H. Lehman to the Saratoga Springs [N. Y.] Authority.

DR. HOWARD R. HANSELL has been appointed Health Officer of Sharon, Conn., during the absence of Dr. JEROME S. CHAFFEE.†

MARY R. LAKEMAN, M.D.,* of Boston, Mass., has been appointed North-eastern Regional Director for the Women's Field Army of the Ameri-

can Society for the Control of Cancer. Dr. Lakeman retired December 1, 1937, from the Massachusetts Department of Public Health, with which she had been associated for 20 years in child and adult hygiene work.

E. V. MCCOLLUM, PH.D.,* Professor of Biochemistry and head of the Department at the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., received the degree of Doctor of Laws at a special convocation recently at the University of Manitoba.

DR. WINFRED OVERHOLSER has been appointed Superintendent of St. Elizabeths Hospital, Washington, D. C.

DR. ERNEST R. PENDLETON has been appointed Health Officer of Granby, Conn.

J. H. SHRADER, PH.D.,* has been elected President of the Metropolitan Dairy Technology Society, New York, N. Y.

DR. A. STAMPAR, of the staff of the Health Committee, League of Nations, Geneva, and formerly the Director of Health of Yugoslavia, recently delivered a DeLamar lecture on hygiene at Johns Hopkins on the subject. "International Health Work."

Southern States

ASA BARNES, M.D.,† has been transferred by the Missouri State Health Department from District No. 3 (Kennett, Mo.), to open up a new district, District No. 6, composed of 14 counties in southwest Missouri; his address is District Health Department, Ozark, Mo.

JOHN B. H. BONNER, M.D.,† of Stony Creek, Va., Health Officer of Sussex County, has been appointed Director of a new health district in Prince George County, with headquarters in Hopewell.

* Fellow A.P.H.A.
* Member A.P.H.A.

ROBERT P. COOKE, M.D.,† of Lexington, Va., is Health Officer of Boteourt County, which has recently joined the Alleghany-Rockbridge Health Department thus forming a 3-county district. The office of the Assistant Health Officer, JAMES H. GORDON, M.D., is located at Covington, Va.

WILLIAM W. FULLER, M.D.,† of Christiansburg, Va., has been appointed Health Officer of Montgomery County.

ARTHUR H. GRAHAM, D.P.H., M.D.,† has been appointed Medical Director of the new district health unit established for the counties of Bullock, Chambers, Lee, Macon, Randolph, Russell, and Tallapoosa, Ala. Headquarters will be in Opelika, Ala. This is a coöperative enterprise between the Alabama State Department of Health and the Commonwealth Fund of New York.

J. B. IVY, M.D., is the new Director of the district health unit for Bradley, Lincoln and Cleveland Counties, with headquarters in Warren, Ark.

DR. EDWARD V. JONES, JR., has been appointed Assistant Health Officer of the Arlington County, Va., Health Department.

RUSSELL H. LYNCH, M.D., of Hollis, has been appointed Health Officer of Harmon County, Okla.

DR. H. B. MAGILL, JR., formerly Health Officer of the Hanover County Health Department, has resigned to enter private practice in Tappahannock, Va.

DR. RUFUS F. PAYNE† has been appointed Assistant Director of County Health Work in the Georgia State Department of Health. Dr. Payne was formerly Commissioner of Tift

County, where he has been succeeded by DR. ROBERT H. HARALSON, JR.† DR. JAMES M. SUTER, of Washington, D. C., has been appointed Health Officer of Lee County, Va.

Western States

DR. ROBERT E. AUSTIN has been appointed Health Officer of Coronado, Calif., to succeed DR. RAYMOND SPEAR.

DR. JAMES W. CREVER, JR., of Susanville, Calif., has been appointed Health Officer of Lassen County, Calif., to succeed DR. CLARENCE I. BURNETT.

DR. WILLIAM R. HICKS is the new Health Officer of the Multnomah County, Ore., health unit.

WENDELL A. JONES, M.D.,† of Riverside, Calif., has been appointed to take charge of the administration of the public health affairs of the city of Banning, under the Riverside County Health Department.

Canada

DR. NORMAN MACL. HARRIS* retired on superannuation, April 1, from the position of Chief of the Laboratory of Hygiene, Department of Pensions and National Health, Ottawa, Canada.

Foreign

DR. WU LIEN-TEH has retired after 30 years' continuous service, from 1907 to 1937. He was Vice-Director of the Army Medical College (China) from 1908 until 1910, when the Manchu Government sent him to take charge of the Manchurian Plague Prevention Service. In 1930 the Government decided to organize a modern Quarantine Service and Dr. Wu was made Director. He served as head of the Plague Prevention Service for 20 years and of the Quarantine Service for 7½ years.

* Fellow A.P.H.A.

Qualifications of a Venereal Disease Control Officer*

THOMAS B. TURNER, M.D.

Staff Member, International Health Division of The Rockefeller Foundation, and Lecturer in Medicine and Lecturer in Public Health Administration, The Johns Hopkins University, Baltimore, Md.

FOR a number of years in some states and in most large cities public funds have been used to support the treatment of indigent syphilitics. Of late, however, this stop-gap medicine has given way to an ambitious program in which the objective is the control of syphilis. That this program offers hopes of success is attested by the experiences in certain European countries and in a few communities in this country, but it is already clear that the development of the program will, for the next few years at least, call for the expenditure of large sums of money. An important element in the success of the program undoubtedly will be the caliber of the physicians under whose direction it is developed. It is not only essential that the best available men be chosen to assume immediate direction of the program but it will be good economy in the long run if these men are given the opportunity

to secure training which will help them to meet the problems peculiar to the prevention and cure of syphilis. I have been asked to state what, in my opinion, should be the qualifications of a venereal disease control officer and to outline briefly the training which will best fit a person to assume a responsible position in a control program undertaken by states or large cities. Since the principles upon which control measures should be based have not been clearly defined for any of the genito-infectious diseases except syphilis, the discussion will be limited largely to the program as it relates to that disease.

The objectives of any syphilis control program, I take it, are twofold: first, to bring about a reduction in the annual attack rate of syphilis, and second, to bring about a reduction in the disability rate and the death rate among persons already infected. The principal measures by which it is hoped to attain these objectives are treatment of the person who is a potential source of infection in order to

* Read before the Health Officers Section of the American Public Health Association at the Sixty-fifth Annual Meeting in New York, N. Y., October 5, 1937.

render him non-infectious, and treatment of other syphilitics, perhaps of all syphilitics, in the hope of preventing or arresting the development of disabling or killing lesions of the disease. The application of these measures, however, is by no means simple, and the venereal disease control officer should be qualified to meet the main problems inherent in the program. One important problem is concerned with the best methods of discovering infected persons, particularly those who are in an infectious stage, and of bringing them under treatment. Another problem is how best to provide scientifically sound anti-syphilitic treatment for all who need it, under conditions which are socially decent and economically practicable. Finally an effort must be made reliably to measure the extent of the public health problem in its broader aspects and the results accomplished by the control program. It is evident that such a program must rely for its execution both upon the practice of so-called curative medicine and the use of methods commonly associated with the field of public health.

Although the syphilis control program is still in the developmental stage in this country, it is probable that in cities and thickly populated rural communities control efforts will be organized on a district basis and that the center of this administrative unit will be the well organized and well equipped syphilis clinic. This center, which may best be built around a hospital clinic, will provide treatment for the bulk of the cases in the district, and will serve as a diagnostic and consulting center for the area. Many other elements enter into a complete program, however. A majority of the cases of syphilis will probably be discovered by private practitioners and in various out-patient clinics of hospitals. Moreover, a fair number of cases will be treated in the offices of practitioners and specialists.

Efficient laboratory service must be available to each of these groups and the work of public health nurses and social workers must be correlated with the general program. Since the district will probably not be a natural epidemiologic unit, it will be necessary to maintain close coöperation between it and other districts. Clearly, therefore, the program must be given cohesion by an administrative officer who is a member of the city or state health department. Intelligently to administer such a program, the control officer must have a good working knowledge of clinical syphilology; he must comprehend the community aspects of the problem, and he should be qualified to collect and analyze data which have a bearing upon control measures and administrative practices.

SYPHILIS IN THE INDIVIDUAL

Except in rather small communities, the venereal disease control officer will not have the responsibility of operating clinics, nor will he be responsible for the immediate care of patients. Nevertheless, the general program is based so largely upon the treatment accorded the individual patient that often it will be necessary for the director of the community program to make decisions which will ultimately affect the clinical management of patients. After all, most of the control measures now in use have been formulated by applying a knowledge of the clinical course of the disease and of the effects of anti-syphilitic treatment to the epidemiologic problems involved. It is important that the person responsible for the application of these measures and for the evaluation of new methods should have a real understanding of the underlying principles upon which these measures are based. In other words, the venereal disease control officer should be in his own right a competent syphilologist.

Competence in the practices of syphilology depends first upon a knowledge of the clinical course of the disease and how to treat it, and second upon the ability to carry out certain technical procedures. All of us, of course, are familiar in a general way with the clinical course of syphilis—the progression through successive stages to clinical latency or to damaging lesions and ultimate death of the individual. But syphilis is a complex disease and within this general pattern there are innumerable variations in its clinical course, and these variations must be interpreted in terms of syphilis control. Likewise, the treatment of syphilis is not simple. A number of drugs are used in a variety of ways. The scheme of treatment differs with the stage of the disease and with the individual patient. Moreover, the toxicity of the drugs themselves raises numerous problems for the syphilologist. The venereal disease control officer should certainly be thoroughly familiar with the uses, limitations, and toxic effects of the drugs which are being used by him or under his direction.

The diagnosis and treatment of syphilis also entail the use of a number of technical procedures which require a fair degree of skill for their proper execution. No clinic can serve its purpose effectively in which intravenous and intramuscular treatment is not skillfully given. Minimum standards require that darkfield examinations for the presence of *Treponema pallidum*, spinal punctures, and physical examination for the presence of cardiovascular or central nervous system involvement be competently performed. The venereal disease control officer will be the better for having mastery of these techniques.

Serologic tests are today the keystone of the diagnosis of syphilis. While these tests are commonly made in central laboratories, it is exceedingly

important that the clinician and the administrator comprehend the fundamental nature of the tests and the safeguards that must be used in their application to clinical syphilology. The recent report of the Committee on Evaluation of Serodiagnostic Tests for Syphilis¹ showed that in 5 state laboratories tests were being used that gave positive results in less than half the specimens obtained from 200 known syphilitics, in 7 other state laboratories positive results were obtained in from 50 to 60 per cent, and in 7 others in from 60 to 70 per cent of specimens. Of graver import is the finding that in 3 state laboratories false positive tests were obtained in 10.1 per cent, 9.1 per cent, and 8 per cent, respectively, of the specimens examined from 100 presumably non-syphilitic individuals. Clearly, methods must be devised for making periodic checks on the sensitivity and specificity of serodiagnostic tests being performed in state, municipal, and private laboratories. Laboratory directors will doubtless welcome the opportunity to make such checks but it would seem to be the responsibility of the venereal disease control officer to initiate and coördinate this type of activity. In order to do this competently he should be thoroughly familiar with the various tests in common use and should understand the technical difficulties which confront the serologist.

SYPHILIS IN THE COMMUNITY

The community aspects of syphilis control may be divided into two broad phases. In the one, which Frost appropriately terms the "proximate" epidemiology of the disease, the problem is largely one of the identification of immediate sources of infection and exposed persons, and of bringing them under treatment. Coupled with this is the question of general case finding, for undoubtedly when a wide effort is

made to uncover cases of syphilis, such as by routine serologic testing by private physicians and in the outpatient departments of general and special hospitals, many actual or potential sources of infection are discovered which would otherwise go unrecognized. This "proximate" epidemiology is largely the immediate responsibility of clinic directors and practising physicians, but it is an important aspect of the general program and for this reason the program director should be thoroughly familiar with the problems involved and the best methods of meeting them. Further than this, however, there are many ways in which the venereal disease control officer can assist and coördinate the efforts of the treating agencies and indeed there is urgent need for active experimentation in this field.

The other broad phase of the epidemiology of syphilis is concerned with problems such as the accurate appraisal of the prevalence and distribution of syphilis in the community, its long-time effects upon individuals, and the relative importance of different factors in its prevalence. It is evident that these represent some of the most difficult and complicated problems in epidemiology, but the control officer is in a favorable position to make contributions to the study of such problems.

Although much has been added during the past 25 years to our knowledge of the manner in which syphilis affects the individual, little precise information is available upon the effect of syphilis on the community. Data on the prevalence or the attack rate of syphilis are relatively meager and consequently it is exceedingly difficult to secure reliable evidence regarding the effect of control measures on these rates. Since control measures will entail the expenditure of large sums of money, it is only reasonable to ask that

the events with regard to syphilis which follow this expenditure be measured in some tangible fashion. No one seriously questions the fact that there has been a substantial reduction in the morbidity and mortality rates from smallpox, typhoid fever, diphtheria, and tuberculosis during the period over which control measures have been directed toward these diseases. The responsibility for obtaining comparable figures for syphilis would seem to rest primarily upon the venereal disease control officer.

In collecting data of this nature it is of fundamental importance that the original clinical observations be correctly made. Except in a few of the better syphilis clinics even basic elementary data, as for example, whether the patient had early or late syphilis cannot today be relied upon. As director of the program, the venereal disease control officer should know what information it is necessary or desirable to obtain, he should make every effort to see that his coöperating clinicians are in a position to obtain this information, and he should be able correctly to analyze and intelligently to interpret the data that are secured. Finally, he should be able to appraise critically the value of existing or proposed measures directed toward syphilis control.

For the venereal disease control officer to deal effectively with these problems he should have a good grasp of clinical syphilology, he should have a working knowledge of bio-statistics, and he should know in what manner epidemiologic data have in the past contributed to the control of other diseases. Finally, this officer should be acquainted with current practice in public health administration.

INVESTIGATION OF PROBLEMS RELATING TO SYPHILIS CONTROL

Although the lines along which syphilis control should proceed seem to

be fairly clear, it is scarcely necessary to point out that new knowledge of the disease may contribute greatly to more effective control. It is important that new facts be sought for in the laboratory, in the clinic, and in the field. Except in rare instances, a venereal disease control officer may have no opportunity to carry out laboratory investigations. Likewise the study of syphilis in the individual patient should probably be attempted only in well organized clinics. The control officer, is, however, in a peculiarly favorable position to make substantial contributions to our knowledge of syphilis in the community. It is not to be expected, of course, that every public health physician interested in syphilis will be able to add to the existing knowledge of the disease. It is highly desirable, however, that every venereal disease control officer should comprehend the main questions upon which it is believed field studies will throw additional light, and as a minimum contribution attempt to collect basic data on these questions in such form that they can later be used either by himself or others. In the selection of venereal disease control officers, then, consideration should be given to those who seem to possess the potentialities for doing investigative work, and in the training of candidates for responsible positions in the syphilis control movement every effort should be made to develop a critical attitude of mind.

THE TRAINING OF A VENEREAL DISEASE CONTROL OFFICER

Training in the clinical and field aspects of syphilis and other genito-infectious diseases can be obtained, of course, without formal instruction by actual work in clinics and in public health departments. The same amount of training, however, can be secured in a shorter period of time and with less effort through the medium of organized

university courses. Such courses should extend over a period of not less than 6 months, preferably 1 year, and in general the work should be largely practical with a minimum of didactic instruction.

Proficiency in the diagnosis and treatment of syphilis can be acquired only by work in a well organized syphilis clinic under competent supervision. Diagnosis in syphilis depends to a much greater extent than formerly upon the skilled use and correct interpretation of a few laboratory procedures, and to a much less extent upon detailed clinical differential diagnosis. Successful treatment depends largely upon striking a happy balance between routinization and individualization in the use of various treatment schemes. These things can be learned by the physician only if he has the responsibility of diagnosis and treatment of individual cases. Under these conditions the average physician, even though long out of the practice of medicine, can within a year acquire competence in syphilology far above that of the average practitioner. During this period he becomes familiar with physical diagnosis as applied to syphilis, with the use of the darkfield microscope for diagnosis, with the technic of doing spinal punctures, and with the preparation and administration of anti-syphilitic drugs. Along with clinical work a period of time should be spent in the serologic laboratory, where opportunity is afforded for actually performing the various tests used in diagnosis.

These accomplishments in an administrative officer may to some seem quite useless, but with them he will not only have a much clearer comprehension of his problems but he can also with assured authority give useful instruction to his *cooperating clinicians*. During the past year I have had the responsibility of supervising instruction offered to physicians whose immediate

interest is in syphilis control. Some of these men have been filling administrative positions while others have been directors of venereal disease clinics. I think it is correct to say that in the opinion of these men the opportunity to work in a well equipped university clinic where emphasis is put upon the careful study of a relatively few patients has been most beneficial.

Just as training in the clinical aspects of syphilis can best be obtained in a teaching clinic, so can training in the epidemiologic and administrative aspects of syphilis be acquired more readily through the medium of a health district which has been organized for teaching purposes. In such a district, problems relating to the prevalence and distribution of the disease, the sources of infection, the most efficient methods of discovering cases of syphilis, and the best methods of providing for their treatment may be studied. As yet only a few broad principles can be taught with any degree of assurance, for on many points there are insufficient basic data on which to establish administrative procedures. The student will profit most by taking an active part in the administrative, epidemiologic, and investigative work in progress in the district. He should become familiar with the type of records in current use and with the relationship of the administrative officer to clinics and private practitioners in the district. He should at some period in his training assume responsibility for contact investigation and follow-up work in the district. He should also become familiar with the functions of the public health nurse and medical social worker in the syphilis control program.

A major portion of the time of the student will then be spent in the clinic and in the health district, but his training should be supplemented by work in related subjects. It is highly desirable that the prospective venereal

disease control officer should be well grounded in the elements of biostatistics and such a course should be available to the student. Likewise, much may be gained by a study of the epidemiology of other chronic infectious diseases, notably tuberculosis. For those who lack a long training in practical public health administration, formal courses in this subject will go far toward elucidating the problems most commonly met and the public health practices which have stood the test of actual experience.

The entire course of training should be given a sense of unity through frequent seminars. These seminars may be used for the group discussion of the field and clinic work and for the more formal discussion of some of the major problems concerned in syphilis control. The literature of syphilis is full of assertions and arguments based on quite inadequate evidence, and it is important that these be examined in critical fashion.

Finally, I feel that every student doing special work in syphilis should have the opportunity to study intensively some particular problem, however small, in this field. The capacity for doing investigative work will vary, of course, with different students and the problems studied must vary accordingly. I am firmly of the opinion, however, that the investigation of some problem is a most valuable educational medium. Almost any problem, whether related to the clinical, epidemiologic, or laboratory aspects of syphilis, has ramifications which will take the curious and industrious student far beyond the bounds of the immediate subject. This type of study is practicable only when the student is in residence for 6 months or longer, and it can only be done under the supervision of instructors capable of guiding the student in the selection and in the study of a worthwhile problem. Many of these studies

may not contribute directly or even materially to syphilis control, but if the study is carefully planned and intelligently developed it will go far toward developing a critical attitude of mind in the student. Moreover, there is always the chance that an occasional student will be stimulated to the point of continuing sound investigative work along with his routine duties in actual syphilis control.

The foregoing discussion has been concerned largely with the duties of the director of the general community program and the qualifications which would seem to be desirable in such a person. Second in importance only to this officer are the directors of the clinics which form the keystone of the control program. The duties and responsibilities of these men have been only alluded to and cannot be discussed fully at this time. It is evident, however, that somewhat the same qualifications recommended for the venereal disease control officer would be equally desirable in a clinic chief. The latter should perhaps be a somewhat more accomplished syphilologist, but it is also important that he fully comprehend the community aspects of the program. Training in clinical syphilology, in the epidemiology of the disease, and in certain related disciplines such as bio-statistics, would prove equally valuable to the clinic director.

SUMMARY

Measures directed toward the control of syphilis entail both the practice of

so-called curative medicine and the use of methods commonly associated with the field of public health. In order soundly to administer such a program the venereal disease control officer should be thoroughly familiar with each of these aspects of the problem. He should have a good working knowledge of clinical syphilology, on the one hand, and bio-statistics, epidemiology, and public health administration as these disciplines apply to syphilis, on the other. Moreover, he should be capable of collecting and analyzing data bearing on syphilis which will aid in rendering control measures more effective.

Training to meet these qualifications can readily be obtained in teaching centers where facilities are available for clinical work in the diagnosis and treatment of syphilis, for study of the epidemiology of the disease, and for the observation of control measures in actual operation. The work should be largely practical, supplemented by a few formal courses and seminars. An important feature of any course of training lasting 6 months or longer should be the opportunity for each student individually to carry out an investigation of some problem related to syphilis and its control, and every effort should be made to develop a critical attitude of mind in the student.

Preparing the Nurse to Meet Community Needs in Public Health*

MARION G. HOWELL, R.N., M.Sc.

*Professor of Public Health Nursing, Western Reserve University,
Cleveland, Ohio*

IT IS rather significant that the discussion of such a group as this should this year direct its consideration to public health nursing education in relation to meeting community needs. At other times we have talked of the preparation of the public health nurse but only recently have we seemed to stress whole community needs. We trust such a title is prophetic and that the time will come when the public will demand and make possible needed public health facilities.

It may be well for us to ask first what we consider community needs in public health. Certainly our ideas of community needs have developed in the last quarter of a century and in direct relation to accepted standards of living, discoveries and new practices in the science of medicine, new methods of transportation, as well as facilities for wider dissemination of knowledge. Education, research, legislation and transportation have figured heavily in the changes in our modern conception of community health. Whereas, epidemics of smallpox, typhoid fever, and diphtheria, were once tolerated as the gifts of the gods, we now have as our objec-

tives not only the control and prevention of communicable diseases but the promotion of health—mental and physical—the organization of communities for community planning, and action in health and social welfare.

In these changing programs the public health nurse assists as a staff member, as a supervisor, or as a director of nursing service in official or nonofficial agencies, and her duties are manifold. In the *A.P.H.A. Year Book, 1936-1937*,¹ we have a report of the Sub-Committee on Educational Qualifications of Public Health Nursing of the Committee on Professional Education, approved by the National Organization for Public Health Nursing and by the Governing Council of the American Public Health Association, which sets forth the minimum qualifications for those appointed to positions in public health nursing in the years 1935-1940. This report emphasizes the changes that are taking place in the basic education of the nurse in the undergraduate school of nursing where there is increased emphasis on the social and health aspects of nursing as an inherent part of the preparation of all nurses. There has since been published a *Curriculum Guide for Schools of Nursing*, which is the result of widespread study and consultation under the leadership of the Committee

* Read at a Special Session of the Committee on Professional Education of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

on Curriculum of the National League of Nursing Education. The title of this new publication and the methods used in its preparation indicate to some extent the professional growth of the last decade.

It has been said that no other profession has made as extensive a study of its curriculum, or has succeeded in organizing so many study and consultation groups throughout the country, with the result that there is now unusual opportunity for better preparation of all nurses and for more careful selection of students accepted by the schools of nursing.

The survey of public health nursing conducted by the National Organization for Public Health Nursing showed the great need for better qualified personnel and stressed the need of better preparation for health teaching. Since schools of nursing control the intake of the nursing profession, and, therefore, the quality of public health nurses, it is highly important for the public health personnel to see the problem as a whole and make wise and concerted effort to bring into the nursing profession that type of young woman who is successful in the public health field—the intelligent young woman from a home of culture where honesty, industry, and integrity are considered important and where tolerance, patience, and faithfulness to duty are practised. Fortunately, more of these young women are today completing high school and college, and are entering nursing when they are more mature and have better preparation for the exacting requirements of the profession. Fortunately also the nurse entering the better school of nursing today has a greater opportunity for learning and for developing nursing skills and for learning more of public health and social aspects of nursing. Some of them study under the direction of qualified public health nurses and some are

fortunate enough to have an affiliation with a public health nursing agency. We may venture to say that today almost all student nurses have better opportunities for preparation in nutrition, in pediatrics, and in obstetrics than ever before, and even so there is much room for improvement.

In considering the community needs in public health today, it may be claimed that in our older programs we have gone about as far as we can until we change our emphasis—for example, the infant welfare program. In some cities the infant morbidity and mortality rates have steadily decreased, and perhaps cannot be further changed to any extent until we attack the problem of early infancy. In the same cities some claim we cannot do much more in the schools until the problems of administration are solved. In the meantime, should we review our generalized programs in an effort to determine which phases need increased emphasis? Should we do more to meet the needs of the community in regard to prenatal and maternity work, including maternal health programs? Should we place more emphasis on the preschool program and the work with cripples? Should we do more in the fields of industry, in nutrition, in mental health, in the prevention of all communicable diseases? Should we do more in community organization? Should we know more about how to study communities, and should we keep better records of our work? If so, we have much to do by way of preparation of both the health officer and the public health nurse.

It is practically impossible, in the basic course in nursing, to give more than the fundamentals of some of these programs since the student's practice is largely confined to the hospital wards, and she has all too little time to learn what there is to learn. It is, therefore, necessary for her to have opportunity

to learn in the public health fields. As you know, we have had so-called postgraduate courses in public health nursing in the United States for the last 30 years and we have today 17 courses accredited by the National Organization for Public Health Nursing. In order to complete one of these courses, the graduate nurse has to give up a year's salary and spend almost its equivalent in meeting the expenses of this postgraduate program. She must also meet university entrance requirements and have recommendations indicating her aptitude for public health nursing. Since such a program is fairly expensive for the average nurse, and since there have been comparatively few scholarships, too small a number of nurses have been able to avail themselves of these opportunities. However, with the provisions of the Social Security Act, a limited amount of public money is now available for public health nursing education, and various plans for its use have evolved.

In a recent statement in *Public Health Nursing*,² the Educational Supervisor of Nursing, New York State Department of Health, has told of their plan which I commend. Miss Blaisdell states that they are approaching the problem in 2 ways:

One is aimed at strengthening the present staff, and the other seeks to add well prepared public health nurses. As a part of the first activity each public health nurse supervisor and administrator in the state is constantly looking for the staff workers who seem especially promising for development, and all public health nurses in the state have been given an opportunity to make known their professional aims and ambitions in a confidential questionnaire sent out by the Division of Public Health Nursing. From these two sources the selection of nurses for postgraduate work is being made.

We are encouraged by noting that

... nurses in state, county, city, school and *nonofficial organizations* are represented among the group who are having this privilege

and stipends are usually given for one semester of college work. In most instances these nurses are required to give at least one year of service to the state in any place requested.

This seems to be a very practical and successful plan in which I would like to make only one change, namely, that those given the stipends be allowed to complete at least a year's study, meeting the added expense from private funds even if they must be borrowed. This plan has these advantages:

1. A year gives the student more time to adjust to a university program.

2. She has opportunity to enroll in courses which run throughout the academic year.

3. The nurse taking her place in the field has more time to adjust to a new field program (this is especially important in a rural area where a new nurse is only fairly well started at the end of 16 or 18 weeks).

4. By making a personal financial investment the student will feel more independent and free from possible political entanglements.

5. Such a plan will safeguard the problem of granting stipends where the nurse is not especially interested in public health nursing.

6. It helps to insure good work on the part of the student.

7. It allows time for the completion of the requirements for a certificate in public health nursing.

Miss Blaisdell has also explained the New York plan of giving experience to beginners in public health nursing by an exchange system with several of the well supervised *private* organizations in the state.

This plan provides that in exchange for each stipend given to one of its selected staff nurses, the private organization takes 2 carefully selected beginners for 4 months of introduction to field work. Each beginner is given half the salary of the staff nurse who

was granted the stipend. The main stipulation is that the organization have a director of the student program who meets the same requirements as the faculty of an approved course in public health nursing.

It seems to me an important provision of this plan is a committee on selection of beginning students, made up of members of the 3 state nursing organizations, together with a representative of the State Department of Health, and one from the Civil Service Commission. In addition to these provisions, there is a state-wide staff education program for all public health nurses in the state.

Other states are experimenting with similar plans, and private and public organizations are encouraging their staff members by granting time for study, and by special staff education programs.

The courses in public health nursing are attempting to strengthen their programs in both theory and practice and, while not minimizing the fundamentals, are adding courses to enable the nurse to know more of her rôle in the control of syphilis, in the care of cripples, in the care of the mentally ill, in health education, and in nutrition. Much needed courses in supervision and administration are developing.

In meeting community health needs the nurse is an assistant, a member of a so-called health unit staff, who is entrusted with the privilege of entering the home, the school, the factory. To many in the community she is the best known representative of the health department or the private agency. Her preparation and service, therefore, reflect the standards of the whole program. The health officer and the taxpayer alike take pride in her success and are baffled by her failures. They expect almost perfection in personal and professional qualifications, with enough knowledge of science to interpret public health to the lay group and enough

nursing knowledge and skill to care for the seriously ill.

Fortunately, this preparation for public health nursing is a continuous process and professional experience with study brings professional development. No one can estimate the value of the present popularity of health. Families and communities are today more health conscious, have a greater desire for health, have an increased appreciation of the value of health, and make more use of hospitals, nurses, and physicians.

As a rule most communities know little, and assume even less responsibility in the selection and preparation of the personnel of their health units. The medical and nursing professions have an opportunity today which is probably without equal in peace times, namely, to secure the intelligent interest and support of our communities to provide financial support, not only for health programs, but also for the preparation of the professional personnel who must administer these programs—to secure their help in encouraging their finest young women to enter the field of nursing, and to have their aid in financing good schools of nursing and public health nursing agencies of high standards. In public health nursing we may say that we are limited only by our own limitations. Concerted effort for community support of nursing education is fundamental. We cannot rise higher than our source.

The success of public health nursing is largely dependent on the type of young woman entering the profession and the opportunities she has for learning.

United and continuous effort for the support of good schools of nursing offering good basic preparation, and the wise selection of students entering these schools will in time give us much encouragement. Nursing education in many countries is focusing on public health nursing and if a committee such

description of these organisms is presented below.

The fundamental requirements for the production of paper having satisfactory sanitary quality are a pure process water; virgin pulp from sound, clean wood, produced and handled under hygienic conditions; and strict control of microorganisms throughout pulp and paper making operations. Certain mills are so situated as to be able to utilize pure mountain water, which is filtered and chlorinated as an additional safeguard. Some mills almost completely eliminate microorganisms, during the entire manufacturing process. The paper from these mills is practically free of microorganisms, slime spots, and objectionable odors, all of which, if present, suggest an inferior sanitary quality.

In many cases a naturally pure water supply is not available, and extra precautions must be taken to prevent contamination of mill systems by undesirable organisms and establishment of slime-forming types in pipe lines, chests, and tanks. Preventive measures are being satisfactorily practised by several mills.

Local conditions at some of these plants render the microbiological control problem particularly difficult. The majority of paper mills making food container board have succeeded in producing board which has low bacterial counts through an effective use of chlorine in bactericidal treatments for pulp and paper making operations.

Sanitary specifications for this grade of paper seem, therefore, to be reasonable and justifiable.

TYPES OF MICROORGANISMS FROM PULP AND PAPER MILLS WHICH PERSIST IN CONTAINER BOARD

A list of the species of microorganisms which predominate in pulp and paper mills has been previously given by the writer.¹ In recent investiga-

tions, samples of container board for milk were obtained under aseptic conditions from paper mill driers, calenders and reels, from which certain representative, constantly recurring species were isolated.

REPRESENTATIVE SPECIES OF MICROORGANISMS ISOLATED FROM CONTAINER BOARD

<i>Bacillus subtilis</i>	<i>Micrococcus ureae</i>
<i>Bacillus cereus</i>	<i>Micrococcus candidus</i>
<i>Bacillus megatherium</i>	
<i>Bacillus vulgatus</i>	<i>Aspergillus niger</i>
<i>Bacillus mycoides</i>	
<i>Bacillus petasites</i>	<i>Sarcina sp.</i>

These and related forms also occur in rinsings from fabricated, moisture-proof containers. Representative isolations include the following:

CONTAINER TYPE A	CONTAINER TYPE C
<i>Bacillus subtilis</i>	<i>Bacillus subtilis</i>
<i>Bacillus cereus</i>	<i>Bacillus cereus</i>
<i>Bacillus mycoides</i>	<i>Bacillus mycoides</i>
<i>Bacillus tumescens</i>	<i>Bacillus tumescens</i>
<i>Bacillus vulgatus</i>	<i>Bacillus albolactis</i>
<i>Bacillus peptogenes</i>	<i>Bacillus megatherium</i>
<i>Bacillus petasites</i>	<i>Bacillus peptogenes</i>
<i>Penicillium sp.</i>	<i>Micrococcus ureae</i>
<i>Oidium sp.</i>	<i>Micrococcus varians</i>
	<i>Sarcina sp.</i>
CONTAINER TYPE B	<i>Actinomyces sp.</i>
<i>Bacillus subtilis</i>	<i>Penicillium sp.</i>
<i>Bacillus cereus</i>	
<i>Bacillus mycoides</i>	CONTAINER TYPE D
<i>Bacillus tumescens</i>	<i>Bacillus subtilis</i>
<i>Bacillus petasites</i>	<i>Bacillus cereus</i>
<i>Micrococcus albus</i>	<i>Bacillus mycoides</i>
<i>Micrococcus aurantiacus</i>	<i>Bacillus megatherium</i>
<i>Micrococcus flavus</i>	<i>Bacillus petasites</i>
Red chromogens (slimy)	<i>Alternaria sp.</i>
<i>Sarcina sp.</i>	<i>Aspergillus sp.</i>
<i>Actinomyces sp.</i>	
<i>Fusarium sp.</i>	
<i>Spicaria sp.</i>	
<i>Aspergillus sp.</i>	
<i>Penicillium sp.</i>	

The microorganisms characteristic of these 4 widely different types of containers are representative as well of the 3 additional types of containers from which isolations were made.

The organisms found in these paper containers undoubtedly originated in the pulp and paper mills since nearly

all of the above species have also been isolated by the author from these sources.

BACTERIAL COUNTS OF CONTAINER BOARD

It has been found that drier temperatures cannot be relied upon to eliminate all of the heat resistant, non-spore-bearing and slime forming microorganisms present in pulp, nor the spore producing species naturally present in appreciable numbers. It is possible to isolate a fairly diversified flora from freshly made board. These organisms may not be present on the outer surfaces of the board, but their numbers can be determined in uniformly disintegrated stock. Various methods of disintegrating board aseptically are available, such as shredders, agitators, and grinders. Bacterial plate counts of disintegrated container board from mills that employ reasonable sanitary control are consistently less than 500 colonies per gram, and this count has been adopted tentatively as standard for this grade of paper.

Where unusually careful attention is

paid to sanitary conditions, results are normally under 100 colonies per gm., even approaching a bacteria-free state. Representative board counts from several mills are shown in Table I.

SANITARY STANDARDS FOR CONTAINER BOARD

The use by mills of paper stock which has previously been employed for commercial purposes (secondary stock) is not consistent with standards of food quality. This statement applies particularly to the use of old board, miscellaneous waste paper and rags. Sanitary control over the product of a mill should include the identification of the fibers used; calculation of dirt content based upon the numerical estimation of dirt in pulp according to methods suggested by the Pulp Testing Committee of the Technical Association of the Pulp and Paper Industry; presence of slime spots identified by microscopic examination; and determination of the bacterial count per gram of disintegrated board.

An application is being made of sani-

tary principles in the production, handling, fabrication, and use of container board and wrappers for various perishable foods besides milk, including other dairy products, shellfish, fatty foods, meats, bread, and breakfast foods.

HANDLING OF CLEAN WRAPPERS AND CONTAINER BOARD

Sanitarily produced food wrapper and container board should be properly protected against contamination from dirt and promiscuous handling. With the aid of protective wrapping for paper and mechanical handling of stock during conversion or fabrication processes, much of the contamination which formerly occurred following paper manufacture is being eliminated. In accordance with the spirit of the U. S. Public Health Service Standard Milk Ordinance, which specifies that after bactericidal treatment all bottles, cans, and other milk or milk products containers shall be protected from flies, dust, flushing water, and direct human contact contamination, container conversion and food plants are reminded that the board which they obtain from the best paper mills has already received, in effect, bactericidal treatment and should be adequately protected from all possible types of contamination.

EXAMINATION OF FABRICATED PAPER CONTAINERS FOR MILK

The present satisfactory paper milk container is sanitarily manufactured from virgin pulp and contains less than 500 bacteria per gm. of disintegrated board. In paper milk container manufacture, the chief sources of microbial contamination are the paper stock and manual contact. With the elimination of the latter through the development of mechanical handling, paper stock contamination continues to be a prominent source of organisms even after impregnation or coating with paraffin.

There is a certain amount of defective paraffining of containers and it is, therefore, not surprising that all types of finished paper milk containers show a few bacteria present. They are present on the inner surface of the container and may consistently contaminate successive sterile 10 c.c. rinses. Practically, however, a single 10 c.c. rinse, made and plated out in conformity with the latest Standard Methods recommended by the American Public Health Association, gives a fairly accurate and indicative count. The examination of containers in actual use by representative dairies provides the best index to the sanitary condition of these containers.

Board which is practically free from bacteria and handled aseptically, yields containers which either produce no growth of organisms, or plate counts between 1 and 15 per container made by plating all of the water from a 10 c.c. rinse on standard agar.

Average plate counts for all types of paper milk containers are usually less than 50 per container. The results shown in Table II are typical of these tests.

TABLE II
Bacterial Content of Fabricated Containers

Container	Number Examined	Per cent Showing No Growth	Approximate Average Count
A	253	44	29
B	172	7	34
C	78	14	9
D	75	12	22
E	156	0	50
F	200	54	4

It is interesting to find very low counts in Container F where much of the container board used is practically bacteria-free.

Considerable attention is also being directed toward the adhesives employed in the manufacture of containers as a possible source of contamination. Perhaps the most satisfactory kind of adhesive, from a hygienic standpoint,

is the synthetic thermoplastic or "hot melt" type of adhesive. However, while some of the gluing and sealing materials in common use are readily subject to attack by microorganisms, it is ordinarily possible to utilize them in forms or grades which do not contaminate containers with microorganisms. Odorous, highly perishable animal glues are obviously not suitable for use in the manufacture of food containers.

Chemical preservatives or germicidal agents are not necessary nor helpful as ingredients in the high quality materials prescribed for paper containers used for food. It is conceivable that certain substances may be employed in the manufacture of container materials which might be retained and exert bacteriostatic or germicidal effects. For this reason the use of such substances or agents should be prohibited unless they have been shown by means of

physical, chemical, or biological tests supported by clinical evidence, to be non-toxic and without effect on milk.

The goal of the present investigation of the sanitary condition of food containers is to produce, if possible, consistently sterile paper and to make sterile containers from this sterile stock. Perhaps this goal is unattainable. We believe, however, that through the coöperation of pulp and paper manufacturers, conversion plants and food industries, and the intelligent enforcement of proper regulations by public health authorities, significant improvements can be achieved in the near future in the sanitary condition of food paper containers used for perishable food products such as milk.

Disintegration of Paper Board for Bacteriological Examination*

J. R. SANBORN

New York Agricultural Experiment Station, Geneva, N. Y.

PUBLIC health officials are interested in a means by which they can determine the bacteriological condition of paper board for food containers. Total bacterial counts furnish one means of judging the probable sanitary state of the pulp and paper mills that produce such paper. The technic described below, developed primarily for use in control laboratories, is convenient, rapid, inexpensive, and applicable to the requirements of routine bacteriological analyses. In order that the usefulness of this technic may be determined and improvements suggested where desirable, this description of the technic that has been used in studies of paper milk containers at the New York Agricultural Experiment Station has been prepared.

For the determination of bacterial counts on samples of paper board used in contact with foods and drinks, such as water, milk, cheese, ice cream, and oysters, it is desirable to utilize a method of disintegration which reconverts the paper to a uniform pulp suspension suitable for distribution in ordinary Petri plates.

DISINTEGRATION APPARATUS

The apparatus consists of a simple mixing or churning device with double

propellers which exert a beating action on the fibers (Figure I). The equip-

APPARATUS FOR PAPER BOARD DISINTEGRATION

ment found most convenient and useful is a modification of an electrically operated food mixer (Powermaster Model 1669, obtainable from Sears, Roebuck and Company, Motor and stand about \$5.00, propellers about \$.25 each). A three-speed motor, used on alternating or direct current voltages, is mounted on a firm base which is used without the revolving disk base and other unnecessary equipment ordinarily supplied with this mixer. The motor case attaches to a hinge pin which allows it to be tilted when the

* Approved by the Director of the New York State Agricultural Experiment Station for publication as *Journal Paper No. 243*, Jan. 3, 1938.

propellers are removed from the can in which the paper is disintegrated.

Before use, the blades of the two propellers should be so adjusted that they mesh while whirling toward each other, producing the shearing or beating action necessary for pulling the fibers apart. Extra propellers obtainable with the motor as beverage stirrers may be adjusted and used in pairs, each member complementing the other in position and pitch.

Square metal jars made from monel metal or other rust proof metal sheets by any tinsmith are used to hold the board as it is disintegrated in sterile water. These are covered with a loosely fitting metal cover and are 7" in height by 4½" square, and hold more than 1 liter. When in use they may be readily set up with a heat sterilized, corrugated paper board cover arranged to fit snugly against the base of the motor. If an ordinary 2 qt. square glass churning jar is used, the arm of the stand may be raised above the base by the introduction of a wooden block between the supporting arm and the base.

PREPARATION OF SAMPLE

Container board samples will ordinarily be collected by health authorities as sheets or as collapsed containers measuring about 9" by 12". These may be collected from milk plants or converting factories by means of sterile forceps and packaged and sealed in sterile paper wrappers or envelopes. Blanks are removed from wrappers with sterile forceps and edges are trimmed with sterile scissors. The margin of the blanks may have a coating of adhesive which means that a strip at least ½" wide should be cut off and discarded. Holding the trimmed blank firmly with sterile forceps, strips of board are cut with sterile scissors and, from these, small pieces of paper are clipped into sterile

receptacles. Other sterile cutting devices may be employed. Sterile 150 mm. Petri dishes may be used to receive clippings. Ten gm. quantities of clipped board are weighed out from the main supply in sterile dishes or beakers, using sterile forceps.

DISINTEGRATION OF PAPER BOARD

Ten gm. quantities of paper board are introduced into the covered metal or glass churning jar with 500 or 1,000 ml. of sterile water. The precise amount of water used will depend upon the nature of the sample and the capacity of containers. The total volume of suspension should be accurately determined after disintegration. Metal jars with metal covers that can be sterilized by autoclaving are preferable to glass jars (See Figure I). If the latter are used it may be necessary, because of the danger of breakage, to sterilize with chlorine solution, after which there must be thorough rinsing of containers with sterile sodium thiosulphate solution followed by a rinse of sterile water.

If the paper board is tough, clippings should be soaked in sterile water at a temperature of less than 40° F. for 2 to 15 hours preferably in a refrigerator. After soaking, the jars containing the paper are immediately adjusted to the churning device with its sterile propellers and sterile corrugated board cover. If the blades are properly set, churning at high speed for 10 minutes should cause complete disintegration of even very tough paper board. Without soaking, tough board may take as long as 30 minutes to disintegrate.

PLATING TECHNIC

In the case of good quality board, 10 ml. amounts of disintegrated stock may be plated with standard agar in 150 mm. Petri dishes. Where board is heavily contaminated, smaller quantities of pulp or prepared dilutions may be plated using regular 100 mm. dishes.

Pulp suspensions should be drawn into the 10 ml. pipettes through the large end or the pipettes should have large openings at the tip. Incubation may be carried on at 32° C. for 48 or 72 hours, or at 37° C. for 48 hours. Counts of colonies are readily made especially where the plates are well illuminated by transmitted light. Colonies of spore-forming bacteria, micrococci, actinomyces, and other heat resisting species of microorganisms are

easily recognized, even in the presence of thin suspensions of pulp.

This technic has already been used in making numerous determinations of the number of microorganisms present in various types of paper and paper board. The results of these tests and their significance will be discussed in subsequent papers. The technic is described at this time in order that others may be stimulated to make similar studies.

Control of Nuisances*

EDWARD WRIGHT

Sanitary Engineer, State Department of Public Health, Boston, Mass.

THE control of nuisances in the up-to-date public health department is in a sense a less important subject than many of the public health problems relating to the control of disease transmitted from man to man. The difference in opinion between the medical man and the non-medical health agent in the fight against disease and in the improvement of the public health was over years ago, perhaps when Chapin pointed out so forcibly that a cesspool is dangerous to health principally when some one falls into it. In the 90's, much of the work of the Massachusetts Department of Public Health was of a sanitary engineering character. While that work has grown very considerably since 1900, the other divisions of state health work of a medical character have grown by leaps and bounds with the vast increase in medical efficiency. This does not mean there is nothing left to be done by the non-medical man in public health, for nuisances and environmental upsets will continue just as surely and regularly as taxes. This was so with our grandfathers and great grandfathers, and the work of the health department is still assumed by many to be largely in nuisance control.

The sense of smell is one that cannot be ignored. Organized cleanliness

is essential for a happy environment and, while the purpose of up-to-date public health work is to prolong life, it is not necessarily advancing it to a high plane unless the sanitarian has an important part in the picture. The American people will doubtless continue to insist that health and comfort be kept together and not be separated by law. The control of a nuisance and the object of sanitary work is not necessarily to prevent injury to health but more largely to promote health in much the same way that a safe water supply may be filtered or otherwise treated to reduce color rather than to remove germs of disease.

Rosenau¹ defines a nuisance as "the use of one's property in such a way as to injure the rights of others, and inflict damages." A nuisance is an annoyance or discomfort. Blackstone has said that a nuisance "is anything that worketh hurt, discomfort or damage." Another noted lawyer has said "a nuisance is whatever the courts find is a nuisance."

Section 152 of the Massachusetts General Laws, Chapter 111, relating to offensive trades, and which in part dates back to 1710, links public health, comfort, and convenience, while Section 143 on the same subject, dating back to 1692, authorizing local departments of health to assign places for carrying on offensive trades links nuisances with matters "hurtful to the inhabitants, injurious to their estates,

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

dangerous to the public health," and those "attended by noisome and injurious odors." The sanitary inspector must consider the magnitude of the offensive condition, the distance to habitations, its frequency and duration, and the unreasonableness of the use of the property before the condition is determined a nuisance. The results of the control of a nuisance while beneficial to the complainants are not spectacular like the correction of a sudden infection of a water supply or the prevention of other forms of infection resulting in an epidemic.

The late George C. Whipple gave much thought to sanitation and its relation to health and life. He felt that sanitation would always be the foundation of sound public health. Many of Professor Whipple's ideas were presented in a paper before the Sanitary Engineering Division of the American Society of Civil Engineers on January 15, 1924.² Another paper of interest on the subject is that of L. L. Tribus on "Odors and Their Travel Habits."³ Still another is that of C.-E. A. Winslow on "The Atmosphere and Its Relations to Human Health and Comfort."⁴ In fact, the American Society of Civil Engineers in January, 1925, held a symposium on the detection and elimination of odors.⁵ In this symposium the law on nuisances is expounded by Irving I. Goldsmith, then Deputy Attorney General of New York. He refers to a decision of the United States Supreme Court⁶ which contains the following statement:

... it has been the settled law, both of this country and of England, that a man has no right to maintain a structure upon his own land, which, by reason of disgusting smells, loud or unusual noises, thick smoke, noxious vapors, the jarring of machinery or the unwarrantable collection of flies, renders the occupancy of adjoining property dangerous, intolerable or even uncomfortable to its tenants. No person maintaining such a

nuisance can shelter himself behind the sanctity of private property.

In summing up Mr. Goldsmith states that,

... The law seems to be adequate to protect the public welfare and enjoyment of property, but resort to the Courts for relief appears to be on the wane for the reason that the skill and ingenuity of the Engineering Profession are eliminating the causes which contributed so largely to the undesirable and unhealthy odors and vapors permeating the air in and about cities and villages. . . .

The control of a nuisance may often be a matter of common sense, but of course the remedy in many instances requires the attention of a sanitary engineer. The health departments in most of the larger cities now have a sanitary engineer on the staff, but the health departments of towns rarely can finance a man as a sanitary inspector of more than high school training, and this service of the local department of health has not been kept so much on the up grade as the other branches. Practically all of the state departments of health, however, now have sanitary engineering divisions and these engineers are equipped to assist the local boards of health in the control of the more complicated nuisances.

As the matter is handled in Massachusetts, a nuisance problem comes before the local board of health first probably by verbal complaint which may rightfully be ignored, and later by signed written complaint which results in an examination by the sanitary inspector. In the large majority of cases, where spite is not involved, the sanitary inspector can readily control the situation either by having the nuisance abated or by making recommendations as to its control. The state department does not go into the matter except to advise the local department upon request or until the local remedies are exhausted, or where two municipalities are involved.

One of the most notable examples involves the intensive industrial district in Everett, Mass., about which complaints have been made by citizens of Everett, Chelsea, Revere, Malden, Medford, Somerville, Cambridge, Arlington, Watertown, and parts of Boston. The causes of these complaints were the odors produced by the very active industries engaged in the refining of oil, the manufacture of various chemicals, particularly sulphuric acid, the manufacture of illuminating gas, and the manufacture of varnish. The first complaint was made in regard to the gas works over 30 years ago. In 1913, in 1922-1923 and again in 1926, numerous complaints were registered with the local departments of health and with the state department. Various improvements were made in the manufacturing processes from year to year, and when the odor elimination devices were given suitable attention, the complaints died out, but as carelessness crept in, objectionable conditions again appeared. In 1932, the Legislature passed a resolve directing the Massachusetts Department of Public Health to investigate the causes of the offensive odors in this district; to determine the effect, if any, upon the public health; and to report the matter to the next session of the Legislature. During the long period of intermittent investigation before the passage of this resolution the matter was taken to the Supreme Court of Massachusetts and the following is quoted from the decision:⁷

... The defendant (Beacon Oil Co., Everett, Mass.) is engaged in a lawful business in the conduct of which it is found that odors necessarily will escape into the air; but it also appears that the defendant has adopted the most approved methods and devices to control and confine such odors at an expense of many thousands of dollars; it also is further found that such odors would not be unbearable or injurious to the health of normal persons. . . . Whether there is a

nuisance in a certain locality depends upon the attendant circumstances, including the character of the neighborhood, the acts complained of and their effect upon the comfort or health of people in general. The district where the defendant's plant is situated has for many years been increasingly devoted to manufacturing purposes; some of the plants were there located many years ago, and from some of them odors are thrown off at times which are offensive and disagreeable, but as those discharged by the defendant are not injurious to the lives or health of normal persons, it cannot be held that a nuisance exists in view of the findings of the master to the contrary.

It is a matter of common knowledge that in thickly settled manufacturing communities the atmosphere is inevitably impregnated with disagreeable odors and impurities. This is one of the annoyances and inconveniences which every one in such a neighborhood must endure. Mere discomfort caused by such conditions without injury to life or health cannot be ruled as matter of law to constitute a nuisance. Each case must depend upon its own facts and no rule can be formulated which will be applicable to all cases. *Rogers v. Elliott*, 146 Mass. 349. *Downing v. Elliott*, 182 Mass. 28. *Stevens v. Rockport Granite Co.*, *supra*. . . .

In the course of the department's investigation⁸ the amount of sulphur dioxide in the air was determined by means of an adaptation of the Palmer dust apparatus operated from a special storage battery with a rotary converter, all carried in an automobile. Of 103 determinations, 31 per cent contained 0.001 mg. or more of sulphur dioxide per liter of air, the highest determination being 0.00897 mg. at a point 0.6 mile from the oil refinery. Careful observations for odors were made in the surrounding territory on the leeward side of the various industrial plants throughout much of the time covered by the investigation—June 27 to November 21, 1932. The time when an odor was noticed was recorded together with the distance from the probable source where it was offensive, and where it was noticeable. The reports also contained information kept

to the character of the odor, the probable source, the mean temperature, the relative humidity at 12 M., and the average wind velocity.

The department was required to determine the effect of the odors upon the public health and comfort and it attempted to detect any possible menace to the public health in Chelsea, Everett, and adjacent areas by studying the data on general death rates, infant death rates, respiratory disease death rates, as well as chronic disease death rates in these and in control areas. This study showed no evidence of any menace to the public health in Everett and Chelsea and the adjacent areas due to the industrial odors, fumes, and gases. Certain of the data in fact were more favorable for these areas than in other industrial areas in the state used as controls. The department obtained information, however, showing that the public comfort in parts of the municipalities was affected by the odors.

During the investigation covering 5 months, only 3 complaints were made to the department of industrial odors, fumes, and gases, and it thus appeared that due to increased vigilance on the part of the plant operators, probably effected by the presence of the department's agents, the odors were kept under reasonable control. Each of the large industrial concerns involved was equipped with a research department engaged from time to time in the development of odor control improvements, and through the efforts of the department various additional improvements were suggested which appeared to effect an improvement. The final result of the investigation was the suggestion that the scientific personnel of the various large concerns in this district continue to devote such time as is necessary to the investigation of odor control devices and to their operation. Most of the industrial concerns

in this region are still in operation but the department has received no complaints for some years.

It is impracticable in this paper to list all of the matters pertaining to nuisance control which require the attention of sanitary inspectors. Rosenau gives the following¹:

- filth
- garbage
- ashes
- slops
- cesspools
- privy vaults
- sink drains
- dumps
- wet and soggy lands
- defective plumbing
- faulty cellars
- overcrowding of tenements
- weeds
- railroad toilets
- salt used on streets in snowy weather
- spitting in public places
- keeping of horses, cattle and swine
- dead animals
- stagnant water

To this list should be added smoke, dust, flies, and mosquitoes.

Of the above list, the matters other than those having to do with sewage disposal, flies, mosquitoes, defective plumbing and overcrowding of tenements probably have comparatively little to do with communicable diseases, but where cesspools overflow onto the surface of the ground, where privies are open to flies and where malaria is present, conditions dangerous to the public health may easily result.

There are many publications on methods of rural sewage disposal. Probably one of the best is *Farmers' Bulletin 1227* of the U. S. Department of Agriculture. On March 26, 1937, the U. S. Department of Agriculture, Resettlement Administration, issued a paper on "Standard Methods and Designs for Sewage and Waste Disposal Installations on Land Development Projects," which is excellent. It goes into the design and construction of

privies, cesspools or leaching pits, septic tanks, Imhoff tanks, sand filters and other methods of sewage disposal. Years of experience have shown that many individuals believe septic tanks to be a cure-all for sewage disposal problems. In fact, certain sanitary engineers feel that when a properly designed septic tank has been constructed the local sewage disposal problem is solved. Septic tanks unquestionably are of value as a preliminary form of fresh sewage treatment but as average domestic sewage is generally over 95 per cent water some means of disposal of the effluent is much more important than the design of the septic tank, and they accordingly should be considered only as a preliminary means of treatment before discharging the effluent into cesspools or sub-surface distribution pipes properly laid in and surrounded by crushed stone or coarse gravel. These distribution pipes should be of adequate length, 20 to 100 ft. per person, depending upon the character of the soil. In designing or constructing a cesspool, information must be obtained first as to the character of the soil and depth to ground water. The location in relation to sources of water supply is of importance, and if 2 or more cesspools are required the effluent from the first should be piped through an elbow or tee taking off from below the flow line. Grease traps are important where kitchen wastes are to be treated.

In the rules and regulations adopted by the Massachusetts Department of Public Health for the sanitary protection of water supplies, no cesspools or other means of sewage disposal are permitted within 50 ft. of the high water mark of any source of water supply or tributary thereof, nor within 250 ft. unless such receptacle is so constructed that no portion of its contents can escape or be washed into such waters. Other rules and regulations

provide that means of sewage disposal should be at least 100 ft. from any pond where bathing is permitted, and at least 200 ft. from any well or spring.

In the construction of a privy, consideration should be given to having the vault water-tight and easy of access so that it can be cleaned when required. The privy should be rain-proof, rat-proof, and fly-proof, located inconspicuously and remote from any water supply. If at no great distance from a well, it should be located at an elevation below the bottom of the well. The contents should be disposed of at places selected by the local health department.

In certain Massachusetts municipalities where difficulty has been experienced in the disposal of night soil, arrangements have been made to convey this material to the nearest municipality having a sewerage system whence it is discharged through man-holes or suitable hoppers, generally with screening devices, into the system. In the construction of the sewerage system of the city of Lynn, Mass., a hopper was provided near the sewage pumping station whereby any night soil or similar sewage material could be discharged through a screen into the sewerage system. This arrangement of conveying the night soil to an adjacent sewered municipality has been consummated in one of the municipalities not having a sewerage system which is located on the watershed of one of the larger water supplies.

Public dumps probably cause as many complaints to the local board of health as any other one subject, due particularly to dust, rats, flies, cockroaches, smoke, and foul odors. The owner, agent, or lessee of any land or enclosure used as a dump, should cause all offensive matter dumped thereon to be immediately covered to the satisfaction of the sanitary inspector, and all other refuse matter should be kept

leveled. Regulations should be adopted whereby no person may dump any offensive material upon any dump unless permitted to do so by the board of health, and all possible care should be used in preventing the escape of dust and papers from the dump or the vehicles used in conveying waste materials to the dump.

Of course, it is impracticable wholly to prevent dumping of foul materials. Individuals sometimes convey waste materials from one municipality into another and in several cases detective work has disclosed tags or other information indicating the source from which the material came.

Dump fires are the cause of considerable offense. The writer has seen smoldering dumps even when they were covered with snow. Experience has shown that the most successful way of combating such a fire is to overhaul the dump by digging trenches with a tractor or steam shovel, and to use a hose stream horizontally. This method has been successful in a dump fire where enormous quantities of used rubber smoldered for several months causing a nuisance in two or more municipalities.

Piggeries have caused considerable difficulty in various suburban municipalities, but the cause is largely with the owner rather than with the swine. If the piggery is suitably isolated and properly controlled, the offensive odors are not likely to cause complaint. It is desirable that the piggery be located on isolated land having a southern exposure where the underlying soil is reasonably porous. An adequate water supply for cleaning should be provided and properly ventilated buildings of substantial construction, preferably painted white and well lighted, should be used. Feeding platforms should be on skids so that they can be readily moved and the ground about the earlier location should be plowed in. A

bin for receiving the garbage should be provided and this should be covered during the warm weather. Garbage cans, wagons, and trucks should be thoroughly washed before they are taken away. Uneaten garbage and manure should be composited with earth and care should be taken when this material is used for fertilizer to plough it into the ground as soon as possible.

The rules and regulations adopted by the Massachusetts Department of Public Health for protecting sources of public water supply provide that no piggery shall be located or maintained within 50 ft. of any source of water supply or tributary thereof nor within 250 ft. thereof unless suitable and adequate provision is made to prevent any polluting matter from flowing or being washed into the water supply. Many of the Massachusetts municipalities have rules and regulations under which swine may be kept only by a permit of the local board of health, which may be revoked at any time for cause.

The keeping of swine has been determined by the Massachusetts Supreme Court as an offensive trade. Others are listed below:

Rendering works	Liquor distilleries
Soap works	Breweries
Slaughter houses	Abattoirs
Oil refineries	Tanneries
Fish handling plants	Varnish works
Glue works	Rubber works
Gas works	Smelters

In the control of offensive trades, the sanitary inspector should aim to regulate rather than to destroy excepting in the comparatively few instances where the business must be absolutely prohibited. Most offensive trade odors can be destroyed by burning under the boilers, by scrubbing with water, or by treatment with chlorine. The Cottrell Electrical Precipitation process whereby solid or liquid particles carried in sus-

pension are removed from gases by a strong electric current has been successful with many industrial odors.

The most important apparatus to determine an odorous nuisance is the human nose used with sufficient patience, and it has been said that a normal person can detect one gram of hydrogen sulphide in 1,000,000,000,000 c.c. of air while mercaptans can be detected 25 times more readily.

Hiscock⁹ gives a budget for the Bureau of Sanitation in a municipality of 100,000 population, to consist of a director, three district inspectors and a clerk with maintenance at a total of 9 to 11.6 cents per capita per year. He states¹⁰ that according to present standards there may be expected 3,000 sanitary inspections and reinspections per 100,000 population per year with abatement in 80 per cent of the cases.

The Massachusetts law on nuisances, General Laws, Chapter 111, Section 122, which was first adopted in partial form at least in 1797, makes the following provision:

The board of health shall examine into all nuisances, sources of filth, and causes of sickness within its town, or on board of vessels within the harbor of such town, which may, in its opinion, be injurious to the public health, shall destroy, remove, or prevent the same as the case may require, and shall make regulations for the public health and safety relative thereto and to articles capable of containing or conveying infection or contagion or of creating sickness brought into or conveyed from the town or into or from any vessel. Whoever violates any such regulation shall forfeit not more than one hundred dollars.

It is interesting to note that the local board of health is *directed* to examine into all nuisances and *shall* destroy, remove, or prevent the same. The Massachusetts law makes no provision for an appeal from the local board of health to the State Department of Public Health, but Section 141 provides that—

Whoever is aggrieved by the neglect or refusal of the board of health to pass all proper orders abating a nuisance, in accordance with any provision of sections one hundred and twenty-two to one hundred and thirty-nine, inclusive, may apply to the county commissioners, who may hear and determine such application and exercise in such case all of the powers of said board. The applicant shall, within twenty-four hours after such neglect or refusal, file with said board a written notice to the adverse party of his intention so to apply to the county commissioners, and within seven days after the filing of said written notice shall present a petition to one of the county commissioners, stating the grievance complained of and the action of the board of health thereon or the neglect or refusal of said board to act thereon, as the case may be. (Chapter 278 of the Acts of 1937)

Hiscock¹¹ points out that the sanitary inspector should strive for a close working relationship between his department and the building and plumbing departments. The collection and disposal of garbage and refuse like the collection and disposal of sewage should be handled by one of the engineering departments of the city rather than by the health department, though the health department, which will doubtless receive most of the complaints due to faulty garbage collection and inadequate sewerage, should be familiar with the procedure as carried on by the engineering department, and should have a hand in preparing the rules and regulations under which the garbage is collected and disposed of.

The collection and disposal of sewage and the distribution of a safe water supply obviously have a more vital relation to the prevention of sickness than does the collection and disposal of garbage and refuse. The writer, in 1932, pointed out that the cost of refuse and garbage disposal for 39 cities in 1930 exceeded the total expenses of the 39 health departments by 12 per cent, and that in 15 of the larger municipalities the refuse and garbage collection and disposal costs in 1930 were

93 per cent of the entire expenses for public health in these municipalities.

Water works are financed on a quantity consumed basis, and in an increasing number of municipalities the use of sewers is paid for on an annual rental basis determined by the amount or character of sewage discharged—which in most instances is a proportion of the water bill based on definite measurements. A service charge based upon the quantity or weight of refuse and garbage collected by the municipality would appear to be a matter for consideration. A board of health in attempting to increase its budget for garbage and refuse collection is likely to be faced with the problem of reducing its budget for more important health activities which should not be curtailed. A service charge would overcome this difficulty.

The late Dr. George H. Bigelow, stated at the meeting of the Massachusetts Association of Boards of Health, that boards of health in certain Massachusetts municipalities were ordering tuberculous patients out of sanatoria at the end of short periods and in some cases refusing to admit new patients, while these same boards of health were spending lavishly to collect garbage, refuse, and ashes which, he stated, have no relation to disease or health, at least in the northern part of the country.

The question of paying for garbage and refuse collection service on a quantity or weight basis rather than from the tax levy might also have the effect of cutting down the quantity particularly of garbage, as has been experienced with water when it has been metered.

Perhaps the most important work for the sanitary inspector is that of education. Progress cannot be made any faster than demanded by the public, and the greatest satisfaction in an educational campaign on the improvement of sanitary conditions undoubtedly relates to the adoption of suitable means for garbage and refuse disposal and the extension of municipal water supply and sewerage systems. Therefore, every opportunity should be used to secure the completion of the municipal water distribution and sewerage systems and the adoption of suitable means of garbage and refuse disposal.

Microbial Flora of Paper Containers^{*}

FRED W. TANNER, F.A.P.H.A.

*Laboratories of Bacteriology of the University of Illinois and
American Can Company, Maywood, Ill.*

PAPER has played an important rôle in storage and transportation of foodstuffs for many decades. Despite the fact that other materials have also been developed for these purposes, treated paper seems to be holding its own, and in some cases to be making great advances. Each material developed for container manufacture has its merits. Paper containers have one distinct advantage over others—they are used but once, and therefore do not present the sanitary hazard inherent in those which are used many times. The one-service container obviates the inconvenience and expense connected with pick-up, washing, and sterilization.

As early as 1908 the advantages¹ and disadvantages of the paper milk bottle were discussed. It was claimed that the paper bottle would reduce the cost of delivery and reduce the possibility of spreading communicable diseases, which may be a serious problem. Before discussing the merits or demerits of a new container for fluid milk, it is wise to appraise the one now in use. Only its public health aspects need be considered. Glass bottles of all types are fomites which may disseminate undesirable bacteria. Hunt² attributed

infection of a milk supply to bottles picked up from homes in which cases of communicable disease existed. Gibbs-Smith and Hobday,³ after infecting milk with *Eberthella typhosa* and placing it in glass bottles, were able to isolate the organism from 2 of 4 bottles after cleaning. If it is possible to substitute a one-service container, a distinct advance will have been made in distribution of one of our most perishable foods.

Cleaning and sterilization of the glass bottle has been studied by milk plant technologists. It has been quite satisfactorily established that there is a lack of relationship between the appearance of a bottle and its microbial load. A major problem is to tell when a glass bottle is clean and satisfactory, largely due to lack of adequate methods in the laboratory for removing bacteria from the inside of the bottle so that they may be counted. A committee of the American Public Health Association (Holmquist, *Chairman*, 1934)⁴ tried to define clean, sterile utensils. Milk bottles were considered at some length. A state health department is quoted as finding 22.6 per cent of 1,820 bottles with counts in excess of 10 per c.c., and 43.1 per cent in excess of 1 per c.c. capacity. Layson, Huffer, and Bran-non⁵ found the bacterial content of washed and "sterilized" glass bottles quite variable. In any case of 12 bottles, 2 or 3 might be sterile, at least

^{*}Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937, and the Fall Meeting of the Society of Illinois Public Healthists in Urbana, Ill., October 23, 1937.

yield no bacteria in a rinse test, while others might yield as many as 180,000 to 200,000 per bottle. High counts were secured from some bottles which looked clean. Gas forming bacteria were found in 14.5 per cent of all bottles examined. The results reported by these investigators, if representative for other dairy plants, indicate that problems relating to bottle cleaning and sterilization have not been entirely solved.

Several authorities have attempted to establish bacterial standards for satisfactorily cleaned and sterilized milk bottles. The International Association of Milk Dealers⁶ required that such a bottle give counts of not more than 2 colonies per c.c. capacity. *Standard Methods of Milk Analysis* (Sixth Edition, 1934, p. 58) in a tentative method for testing sterility of glass bottles provides for not more than 1 colony per c.c. as determined by rinsing the bottle with 100 c.c. of sterile water. This would mean a standard of not over about 1,000 bacteria per bottle. It is necessary to keep these facts in mind when appraising the paper milk bottle.

We may now proceed to appraise paper containers for distribution of fluid milk. Attempts to develop a satisfactory paper container are not new. For some 30 years, if not longer, more or less interest has been exhibited in this possibility. It remained, however, for bottles developed since about 1929 to appeal to any extent to health officers and dairymen. All of our work has been done with one type of container, but since it is made of paraffined paper board, we believe that our experience is little different from that which would be secured with other containers of similar manufacture.

Paulsen⁷ reported that certain Danish dairies were delivering milk in cardboard bottles which had been paraffined inside and outside at a temperature of about 105° C. (221° F.).

Milk from the paper bottles was said to be on the whole bacteriologically equal to that stored in glass bottles sterilized by steam or chlorine, and was vastly superior to milk stored in only well washed glass bottles. The cardboard bottles were absolutely air-tight and did not affect the taste of the milk.

Paper containers for various foods have not been subjected to careful bacteriological examination to any extent despite the fact that they have been used for many years. In most cases their bacteriological condition has been taken for granted. Dudderidge⁸ made such examination after pointing out that the paper used in such dishes was waste paper frequently of questionable origin and cleanliness. She also stated that water-proofing materials might make it easier for bacteria and dirt to stick to the bottle. Her technic consisted in placing the entire dish to be examined in a wide-mouth stoppered bottle containing sterile water and sterile shot. The bottle was then thoroughly shaken and the rinse water plated. A wide variety of microorganisms was isolated including staphylococci, chromogenic organisms, and yeasts. *Escherichia coli* was isolated from one paper dish and one wood-pulp dish. From 400 to 700 bacteria were reported per dish. Wooden dishes yielded fewest organisms.

Rice⁹ was led to study bacteria on milk bottle caps by fluctuating counts in pasteurized milk and appearance of sweet curd milk. Rice examined paper board caps used for closing the bottles. The caps were received in sealed tubes, opened in the laboratory, and every 50th cap selected for examination. The culture plates were prepared by covering the bottom with about 10 c.c. of melted agar which was allowed to harden. The cap was placed on this and 10 c.c. more of melted agar poured over it. This technic soon showed that the cap might be a source of bacteria.

Caps of all manufacturers were quite alike in this respect.

The types of bacteria were somewhat varied and according to Rice were saprophytes of no sanitary significance. The simpler the cap, the fewer bacteria were found. Bacterial growth always developed from the margin of the cap except where the paraffin was broken. Rice believed that the bacteria found were related to the manufacture of the paper-board itself. In order to prove this, Rice had a manufacturer cut pieces of paper-board with sterile instruments and ship them to him under sterile conditions. Bacteria were found especially common in samples the edges of which had been frayed and torn. While it was believed that paraffining caps might eliminate the bacteria or prevent them from entering the milk, just the opposite effects were secured—more bacteria appeared about the edges of the caps. It was explained that the hot paraffin had driven them from the center of the cap to the edge. Rice¹⁰ reported further on the source and origin of bacteria on caps. Aseptic specimens were collected at 2 paper-board manufacturing plants, both of which were using imported sulphite pulp and a domestic pulp board. These were thoroughly mixed in the beaters. Acid sizes caused a greater reduction in bacteria than more alkaline sizes. The heat on the paper making machine contributed greatly to reduction of bacteria. Contaminated water used at the calender stacks gave a public health aspect to the problem. Purification of this water caused a reduction in bacteria on the caps. The finished caps were found to be frequently contaminated by the chip-board tubes in which they were shipped and Rice advised use of cap-board for the tubes.

In another investigation paper milk bottles from 4 different manufacturers were examined bacteriologically by

Rice.¹¹ The bottles were filled with pasteurized milk under commercial conditions, milk in glass bottles being used as controls. One hundred and thirty-five bottles were filled with sterile water and, after incubation at 37° C. for 6 hours, the water was plated. Rice did not use the present methods of rinsing the bottles with sterile water and, consequently, it is difficult to determine the exact bacterial load in the bottles. He believed that bottles made and sealed in the factory were better than those shaped and finished in the dairy.

A Conference on Sanitation of Paper Milk Containers held at the New York Agricultural Experiment Station at Geneva, N. Y., on July 12, 1937, considered all problems relating to manufacture and use of paper milk bottles. This Conference was attended by 60 or 70 individuals representing paper companies, container manufacturers, and health officers. Breed¹² summarized the action of the Conference. Those who are especially interested in paper milk bottles should by all means read this report. This Conference gave special attention to bacteriological examination of paper containers and specified that the latest standard methods of milk analysis recommended by the American Public Health Association should be used. Quart containers were to develop not more than 1,000 colonies; pint containers, not more than 500 colonies; and half-pint containers, not more than 250 colonies. These were said to be in accord with the standards suggested by the American Public Health Association for glass bottles.

While paper stock of questionable origin may have been used for manufacture of some food containers, this is not the case for milk bottles now being manufactured. Only virgin chemical or mechanical pulp is being used, which contains very few microorganisms since the treatment given it

makes it impossible for many micro-organisms to survive. Those which do appear are harmless saprophytes. Anyone familiar with methods of paper making realizes how difficult it is for bacteria to survive chemical and heat treatment which is given the pulp on its way from the heaters to rolls of finished paper. To produce paper of satisfactory sanitary quality it is necessary to use pure virgin pulp, and to handle it in pure water treated, if necessary, by filtration and chlorination. The moisture content of the web of paper leaving the last press for the first dryer is about 75 per cent. The temperatures attained on the drying rolls are such that living bacteria are greatly reduced in numbers. Few survive, and it is probable that paper manufacturers in the near future will supply sterile paper board. Sanborn¹³ has pointed out some necessary improvements. Some of the bacteriological problems inherent in paper containers for foodstuffs are apparent. Their significance must be weighed, however, only in relation to other sanitary features. Conclusions reached as to their merits must be algebraic sums of all factors involved in production and distribution of foodstuffs not only in them but in other containers.

The first situation which an appraisal of paper milk containers from the bacteriological standpoint brings to mind, is the paper-board stock from which they are made. Distribution of such a perishable food as milk in paper bottles has given all such containers new interest. Manufacturers realize that new problems have been added. They must consider the public health aspect of their industry and furnish a product which will meet the requirements of a rigorous health protection program.

The first problem for a bacteriologist is selection of a method. Obviously the

interior of the bottle is most important because only that portion contacts the milk. Methods may be grouped as follows:

1. Rinsing Methods—These methods have been used by many investigators. *Standard Methods of Milk Analysis* (Sixth Edition, p. 58), lists a tentative rinse method for testing sterility of milk bottles. One hundred c.c. of sterile water are introduced into the bottle, the bottle capped, and shaken vigorously to wet the entire surface of the bottle. Two 1 c.c. portions are then plated on plain agar. The number of colonies developing on each plate multiplied by 100 equals the estimated number of colonies per bottle. In our early work, Dr. Wheaton tried a 10 c.c. rinse and found it had considerable merit. He called attention to the fact that a 1 c.c. portion of 100 c.c. rinse water might introduce a great error, for it might not be a truly representative portion, and suggested that the entire 10 c.c. be plated either in 3 plates or in 1 plate. Dr. Tiedeman suggested this modification in a report before the Public Health Engineering Section. This means that a little less than 9.5 c.c. will be removed from the rinsed bottle.

Another method using sterile skimmed milk in place of sterile water has been used by Clark. It was believed that sterile milk might wet the paraffin surface more efficiently than sterile water and thus remove more bacteria. While this seemed to be the case, the plates were so opaque that it was difficult to count the colonies. It was noticed in practically every trial that many more bacteria were demonstrated to be present.

Plain broth was also used by Clark. It was plated in the usual manner, and had the advantage of removing more bacteria from the paraffin surface than water.

II. Direct Examination Methods—Another method is one which has been used by bacteriologists in different fields. It involves introduction of the fluid agar medium into the bottle, shaking thoroughly, and either coating the interior of the bottle with a layer of agar or allowing it to harden in the bottom of the bottle. After incubation the colonies may be counted. This is probably not a good routine method to be used in different laboratories. It is difficult to count colonies, for spreaders may interfere.

Speck and Black¹⁴ found the swab method more practical for the examination of open-top paper containers than rinse methods. They swabbed the surface with one moist and one dry swab. After use, the swab was thoroughly broken and disentangled in a 40 c.c. dilution blank. This technic would be especially suitable for open-top containers but might have decided limitations with containers that are practically closed.

After examining thousands of bottles both during development and after they had been subjected to practical use on a large scale in the New York Metropolitan District, we are convinced that a rinse test is best for routine purposes. This method may not indicate all the bacteria present, but when carried out under standard conditions yields satisfactory results, and indicates quickly whether a container is reasonably free of microorganisms.

When investigations were first started on a container for fluid milk made from paraffined paper-board, it was believed that hot paraffin at a temperature of 82.2° C. (180° F.) would yield a sterile surface. Early work soon proved this expectation to be unfounded, and it has been proved beyond doubt that paraffin is not a sterilizing agent. Paraffin does, however play an important rôle in manufacture of a container

for fluid milk and has many fine qualities. When applied at 82.2° C. (180° F.) it causes a marked reduction in numbers of viable microorganisms. It also prevents many bacteria from gaining access to the milk by entraining them. These observations on the finished milk bottle are supported by many data collected with pure cultures of microorganisms in hot paraffin.

One of the first questions asked about paper milk bottles is, "Are they sterile, and if not what are their bacterial loads, and what types of bacteria are present?" Over 90 per cent of the bottles which we have examined yield no bacteria to sterile rinse water when examined according to the method given in *Standard Methods of Milk Analysis*. This probably does not mean that all of them are free of bacteria but that the rinse test did not show their presence. Most of the bottles which show any bacteria contain fewer than 10 per bottle. A few have given higher counts, such as 190, 70, 80; but the counts have always been well within any standards which have been proposed for glass bottles. The types of microorganisms are not especially significant—sarcinae, white staphylococcus, aerobic spore-forming rods, and non-spore-forming rods. Molds have been encountered in a few bottles. The organisms present are harmless saprophytes apparently picked up by the paper and paraffin.

Over 1,200 bottles were examined in one series for presence of *Escherichia coli* by placing 5 c.c. of the rinse water in sterile lactose broth. The organism was never found.

CONCLUSIONS

1. The average bacterial content of paper milk containers for distribution of fluid milk is much lower than the counts which have been reported for some glass bottles. They are usually less than 10 per bottle.

2. The types of bacteria are usually sarcinae, white staphylococci, aerobic spore-forming rods, and non-spore-forming rods. Such organisms are of no sanitary significance.

3. Methods of making paper-board, while not always yielding a sterile product, cause a profound reduction in numbers of viable bacteria.

4. Water-proofing the paper-board with hot paraffin also contributes a marked reduction in viable bacteria.

5. The bottles studied in this investigation were made and sealed in the factory. That part which comes into contact with the milk is not exposed to contamination, for the containers are not opened until they are about to be filled.

6. The paper container studied in this investigation represents a distinct advance in methods for distribution of fluid milk. It obviates collection of used containers from homes of all grades of cleanliness, and prevents re-use of bottles which have been misused.

Diagnosis of Industrial Skin Diseases*

LOUIS SCHWARTZ, M.D., F.A.P.H.A.

Medical Director, U. S. Public Health Service, New York, N. Y.

IT is important to determine whether a dermatitis from which a worker is suffering is of industrial origin—(1) because it has a direct bearing on the treatment of the case and on the prevention of its recurrence; (2) because of the compensation involved; and (3) in order to determine who pays the physician's fee.

If it can be determined that the dermatitis is due to exposure to certain occupational skin hazards, then the major portion of the treatment consists in preventing further contact with these hazards, that is, removing the patient from his working environment, or providing him with suitable protective clothing. In these cases the prevention of the recurrence of the disease consists in preventing contact with the offending material either by methods stated above or by installing proper safety measures, such as totally enclosed processes, adequate ventilation, clean work rooms, clean clothing, etc.

The compensation laws in many of the states are so worded that if a physician undertakes to treat a worker and he makes a diagnosis that the disease is of industrial origin, then his fee is practically taken care of either

by the compensation commission or by the insurance carrier. But, if after treating the patient, the physician should determine that the dermatitis is not of industrial origin, the employer or insurance carrier will not pay for the treatment, and the physician must look to the patient for his compensation. You can readily see that this has a tendency to make the physician lean toward a diagnosis of industrial dermatitis because very often his chances of being paid a fee by the poor worker is uncertain. It is to the advantage of insurance carriers and compensation boards to devise means to remedy this condition.

There is no one factor upon which a diagnosis of industrial dermatitis can be made. In most instances the appearance of the lesions gives no clue to the irritant. Especially is this so in the acute and chronic eczematoid types of occupational dermatoses. All of the following factors must be considered and each one forms only a link in the chain of evidence on which a diagnosis of industrial dermatitis should be made:

1. *History*—The history of the dermatitis is most important. In order for the dermatitis to be considered as of possible occupational origin, it must be brought out that such a dermatitis was not present before the patient entered on the occupation. It must also be shown that the dermatitis developed during the period of indus-

* Read at a Joint Session of the National Society for the Prevention of Blindness and the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

trial exposure, or after a lapse of a reasonable incubation period since the cessation of exposure. This incubation period should not be over a week. If the history shows that other workers similarly employed are similarly affected, or that new workers at the process are usually similarly affected, then the possibility of a diagnosis of industrial dermatitis is strengthened. If the history should disclose the fact that the patient has had similar attacks of dermatitis previous to the present exposure, then the possibility of the present attack being due to his occupation is weakened, but not necessarily entirely done away with, because it may be possible that in his previous employment he may have met with the same irritant or conditions which are now causing his dermatitis. Knowledge by the physician of the working processes in which the patient is engaged and the substances with which he comes in contact is important, because this enables him to know whether the worker is exposed to known irritants or to conditions which tend to cause dermatitis. For instance, if a worker appears with a dermatitis of the hands and forearms and states that he works on a rubber mixing mill, then we know that he is exposed to irritant rubber compounds and is more likely to develop an occupational dermatitis than is a rubber worker who handles only cold vulcanized rubber objects. If the history shows that the dermatitis develops whenever the worker is at work, gets well or improves when he is away from work and again recurs when he returns to work, then the history itself establishes a definite cause and relation factor between the occupation and the dermatitis.

2. *Site of Eruption*—The site of the eruption is also important. In examining patients, they should be completely divested of clothing. This may in many cases reveal areas of dermatitis

on portions of the body not complained of by the patient and may give the clue to a proper diagnosis. Occupational dermatitis usually begins on the exposed parts—the hands, the fingers and the forearms, if the offending material is a solid or a liquid; and also on the face and neck, if it is a vapor. The covered parts of the body may also be affected, if fumes or vapors penetrate the clothing, or if the clothing is not frequently washed and becomes saturated with irritant chemicals. Thus, dermatitis may occur on the body of the worker handling irritant dusts which penetrate the clothing, such as finely powdered rubber compounds; or dermatitis may occur on the covered parts of the body when the clothing becomes saturated with petroleum oils and waxes, especially if the worker does not take daily cleansing baths and if he does not change his work clothes daily.

Occupational bacillary infections such as erysipeloid of butchers and verruca necrogencia of cadaver handlers also usually occur on the hands. The malignant pustule of anthrax among hide and leather handlers usually occurs on the head, face and arms.

Occupational dermatitis is also often found at points of friction on the body. The wrist where the ends of the gloves or the sleeves rub; the belt line where the belt or the top of the trousers causes friction; the ankle at the shoe tops; and the neck at the collar line, are all sites where friction aids the action of industrial irritants. Sometimes a dermatitis of undoubted occupational origin may become generalized. This occurs when the irritant is one to which the worker has developed a high degree of sensitivity. Many substances are known to be sensitizers. Nitro, nitroso and the chloro compounds are notorious sensitizers. In such instances a primarily localized dermatitis or burn may also sensitize the

patient and a few days later a generalized dermatitis may develop.

3. *Characteristic Appearance of Lesions*—An industrial dermatitis of the acute eczematoid type begins as an erythema followed by papules and vesicles and, when the vesicles break, by an oozing and crusting, no matter what irritant is the cause.

Occupational mycotic infections, such as ringworm among bath attendants, barbers, beauty parlor operators, and yeast infections among cannery workers, usually occur on the hands, but the appearance is not different from that of ringworm or yeast infections of non-industrial origin.

There are, however, a few classes of industrial irritants which produce more or less characteristic lesions on certain portions of the body. Paronychia and onycholysis are common lesions among fruit and vegetable canners. The chlorinated naphthalenes and diphenyls produce acne-like lesions on the face and on the parts of the body which come in contact with the work clothes if the work clothes are not frequently washed and changed. Certain tar compounds also cause acne-like lesions on the exposed parts. Oils cause folliculitis and boils, especially on the hairy portions of the body. Paraffin, grease and tar cause keratoses to develop on the hands and forearms and these keratoses occasionally become malignant. However, the scrotal cancers reported in England as occurring among mule spinners and chimney sweeps have not been noted in this country. Certain hygroscopic chemicals, such as sugar, salt and lime which remove the water from the skin, and solvents, such as the petroleum distillates which remove the fat from the skin, may over a long period of time cause dry, fissured eczemas. Exposure to certain aniline derivatives, such as alpha naphthylamine and benzidine, are known to have caused malignant growths. Gehrmann

has reported papillomata of the bladder among the workers exposed over long periods of time to such aniline derivatives. Arsenic, especially if taken internally, has also caused new growths in the form of keratoses and epithelioma, particularly on the palms and soles. Keratotic lesions and excessive pigmentation around the face and the neck may be occupational among workers exposed to the sun, such as farmers and sailors.
